Abstract

Background: Malaria, babesiosis, trypanosomosis, and leishmaniasis are among the most life-threatening parasites, but the range of drugs to treat them is limited. It is then urgent to have an effective, safe drug with a large spectrum of activity at a low cost.

Methods: For this purpose, an aryl amino alcohol derivative called Alsinol was resynthesized, screened *in silico* and tested against *Plasmodium*, *Babesia*, *Trypanosoma*, and *Leishmania*.

Results: Alsinol was easy to synthesize, following the Lipinski and Ghose rules calculated *in silico*. It had schizontocidal activity against *P. falciparum* and was able to inhibit gametocytogenesis, being particularly active against late gametocytes *in vitro*. On malaria-infected mice, it showed a dose-dependent activity similar to chloroquine. It was also as active as reference compounds against *B. divergens*, and against promastigotes and amastigotes stages of *Leishmania* *in vitro*. It also inhibited the *in vitro* growth of two African animal strains of *Trypanosoma* but was ineffective *in vivo* in our experimental conditions. It showed acceptable toxicity in J774A1 and Vero cells models.

Conclusion: Alsinol is inexpensive to produce, has a large spectrum of activity with an interesting toxicity index. Nevertheless, crucial challenges remain to be faced: the description of a suitable clinical formulation and the determination of the safety margin in preclinical models.

Keywords: Antiprotozoan; Alsinol, *Babesia*; Cytotoxicity; *Leishmania*; Malaria; Oral administration; *Plasmodium falciparum* gametocytes; *Trypanosoma*.

Introduction

After almost 70 years of extensive campaigns of insecticides and utilization of antimalarials, *Plasmodium* is still a cause of great concern for public health. Although artemisinin and its derivatives represent major progress in the therapeutic arsenal, cases of resistance have been already registered.^{1,2} Consequently, the search for alternatives is still on the agenda of Medicines for Malaria Venture, in particular drugs capable of eliminating sexual forms, thus blocking the disease transmission cycle.³

Advances in knowledge of the genome and parasite metabolism have established that there are biochemical and physiological processes common to different parasites.^{4,5} Unlike eukaryotes, the majority of protozoan parasites require essential salvage pathways for purine synthesis due to their involvement in the process of replication. Examples of these are the pathways involving the enzyme adenine phosphoribosyl transferase, which use adenine as a specific substrate, and the pathway involving hypoxanthine, guanine, phosphoribosyl transferase, which uses hypoxanthine and guanine as substrates.

The first one is a common pathway for *P. falciparum*, *B. divergens*, *T. brucei*, *T. congolense*, *T. cruzi* and *T. vivax*, while the latter is for *B. divergens*, *T. brucei* and *T. cruzi*.⁴ DNA topoisomerases, involved in DNA replication, transcription, recombination and repair processes are also potential targets e.g., camptothecin, acts as a class I inhibitor, producing the formation of covalent enzyme-DNA complexes and causing cellular apoptosis of *P. falciparum* and *T. brucei*.⁵ Consequently, drugs targeting one or more biochemical processes

common to different protozoa could be the “magic bullet” against different species respecting the host who takes specific biochemical pathways.

Synthetic compounds can be designed in such a way that they can be cheap, effective (at least in theory) and target some specific metabolic pathways of parasites, i.e., being potentially less toxic against the host.

In an attempt to find a new antimalarial with such characteristics, a series of 1-aryl-3-substituted propanol derivatives (APDs) were designed, synthesized and evaluated previously by us.⁶⁻⁹

Among the most active APDs against *Plasmodium in vitro*, one caught our attention: the 1-(4-Fluoro-phenyl)-3-[1-(4-nitro-2-trifluoromethyl-phenyl)-piperidin-4-ylamino]-propan-1-ol hydrochloride also well-known as Alsinol. We describe herein its synthesis pathway, chemical characteristics, *in silico* screening, activity against different laboratory models of *Plasmodium* growth and extend our study to *Babesia*, *Trypanosoma*, and *Leishmania* that are sensitive to aryl amino alcohol.

Materials and methods

Chemistry

Synthesis (Figure.1)

Figure 1: Synthesis of Alsinol 1-(4-Fluoro-phenyl)-3-[1-(4-nitro-2-trifluoromethyl-phenyl)-piperidin-4-ylamino]-propan-1-ol and chemical structure.

The method used for synthesizing Alsinol is presented in Figure 1. The synthetic method has been published previously.^{6,8,10} Non-commercially available arylamine was synthesized using BOC-amine and 2-fluoro-4-nitrobenzotrifluoride by an $\text{Ar-S}_{\text{N}}'$ reaction via Meisenheimer complex and subsequent removal of the BOC-group with HCl and acetic acid. The methyl ketone 4'-fluoroacetophenone was commercially available. The ketone intermediate was prepared by condensation of the methyl ketone 4'-fluoroacetophenone with the aryl amine via Mannich reaction. The hydroxyl derivative (γ -amino alcohols) was obtained by reduction of the corresponding carbonyl group with NaBH_4 in methanol.

Separation of enantiomers (Figure 2)

Figure 2: separation of Alsinol enantiomers, the first peak is around 99 % enantiopure (left) and the second around 98 % (right).

The synthesis of Alsinol leads to 2 enantiomers that have been separated at the *Laboratoire de Synthèse et Physicochimie de Molécules d'Intérêt Biologique*, Toulouse, France.

The separation was conducted on chiral column Chiralpak IC column packed with 3μm silica particles immobilized with cellulose tris (3,5-dichlorophenylcarbamate). Chiral separations

were carried out on an Acquity UPC² system from Waters for control analysis and on Prep80q system from Waters for preparative enantioseparations. The best elution conditions were with 20 % of isopropanol + 0.1 % of DEA as an additive in a CO₂ mobile phase. The analytical flow rate was 3.5 ml/min. The outlet pressure was 130bar on UPC² equipment from Waters. The injector valve was supplied with a 10 µL loop. The columns were thermostated by an oven regulated at 40°C. The automatic back pressure regulator was maintained at 130 bar. The PDA detector was carried out at 342 nm. Injection volumes were 10 µl for analytical scale.

In silico study

Alsinol was introduced in the Lilly Open Innovation Drug Discovery platform (OIDD).¹¹ The molecular structure of Alsinol was processed following the Lilly Medicinal Chemistry Rules comprising a set of 275 rules, developed over 18 years, to identify compounds that may interfere with biological assays, allowing their removal from screening sets. On Lilly, the computational platform molecular structure of Alsinol was converted to a set of descriptors or "fingerprints" and compared to the full set of all fingerprints previously submitted to the OIDD program. Lilly MedChem Rules are used to identify and discard pharmaceutically undesirable motifs,¹² as is done at many pharmaceutical companies.¹³

Bioactivities

Chemicals

Chloroquine diphosphate (CQ), primaquine (PQ), doxorubicin, miltefosine, amphotericin B, hypoxanthine and N-acetyl-D-glucosamine were acquired from Sigma[®], Imodocarbe dipropionate (Carbesia[®]), was purchased from MSD Animal Health (France), Diminazene aceturate (Veriben[®]) was acquired from Ceva-Libourne, France and SYBR I was from INVITROGEN[®]. Hypoxanthine was prepared as a stock solution at 10 mM. SYBR I was prepared as a stock solution in DMSO at 100X concentration which was stored at -20°C

protected from light and thawed immediately before use. The lysis buffer consists of a solution of Tris (20 mM), EDTA (5 mM), saponin (0.008% [w/v]) and Triton X-100 (0.08% [v/v]), which was previously prepared, adjusted to pH 7.5 and stored at 4°C.

Parasites and cells

The W2 strain of *P. falciparum* and *Babesia divergens* Rouen (1987), *Leishmania infantum*, Vero cells, HepG-2 (Human hepatocellular carcinoma cells) and the Macrophage-like cell line J774A.1 were obtained from the University Paul Sabatier Toulouse III (France), *Plasmodium berghei* (ANKA), was obtained from the Institute of Immunology of the University of the Valley, San Fernando; *Trypanosoma congolense* IL3000, *Trypanosoma brucei brucei* Antat 1.1 and cultivation protocol were kindly provided by Dr. Loïc Rivière and Nicolas Plazolles (UMR CNRS-5234, University of Bordeaux). *Trypanosoma congolense* IL1180 was obtained from Intertryp unit and International Research Center on Livestock Development in the Subhumid Zone of Burkina Faso.

In vitro studies

Antiplasmodial activity against sexual stage of Plasmodium

Production and maturation of gametocytes

The W2 strain (Indochina strain, chloroquine-resistant) of *P. falciparum* was kept in continuous culture in the laboratory, according to Trager and Jensen.¹⁴ The parasitized red blood cells (pRBCs) were grown in 25 ml flasks (Corning Costar Corporation®, USA), containing 8.5ml of RPMI 1640 medium, 0.7ml of Human Serum, 0.1ml L-glutamine and 400 ml of parasitized blood (hematocrit = 4%). Parasitemia remained between 0.5 and 4% (about 2%). Adjustments were made with non-parasitized red blood cells (Red blood cells and human serum were obtained from EFS, Toulouse, France). Cultures were incubated at 37 °C in an atmosphere of 5% CO₂ and a humidity of about 90%. The medium was renewed every day and a microscopic control (1,000 X) of the parasitemia was carried out employing a blood smear fixed with methanol and colored with Giemsa.¹⁵ The culture was synchronized with 5%

sorbitol. The production and maturation of gametocytes *in vitro* were performed according to Ifediba & Vanderberg,¹⁶ Chevalley et al.¹⁷ and Amoah et al.,¹⁸ with minor modifications.

Gametocytes viability assay

The test was carried out with serial dilutions of Alsinol (0.4 to 420 μ M) in a 12 well plate on D+14 gameto stage, parasitemia 0.2%, hematocrit 25% and 20% Human serum, incubated for 48h at 37° C, in 5% O₂, 5% CO₂, and 90% N₂. Primaquine (22 μ M) was used as a control. The gametocytaemia corresponding to each dilution was evaluated by microscopy, and the IC₅₀ was determined by a regression model.

Gametocytogenesis inhibition test

Production and maturation of gametocytes were followed up until D+8. The test was carried out as for a Gametocyte viability assay. Gametocytogenesis was evaluated morphologically using Giemsa-stained blood films corresponding to each dilution, and the IC₅₀ was determined using the regression model.

Antibabesial activity

Babesia divergens Rouen 1987, was cultivated according to Gorenflot et al.,¹⁹ with some modifications. Red blood cells parasitized were grown in 25 ml flasks (Corning Costar Corporation®, USA), with 4.5 ml of RPMI 1640 medium, 0.5 ml of human serum, and 250 ml of parasitized blood (5% hematocrit) at 37°C in 5% CO₂. The medium was renewed every day and a microscopic control (1,000X) of the parasitemia was determined on Giemsa stained smears.¹⁵

The sensitivity to the drug was determined on 1.2% parasitaemia, with Alsinol concentrations ranging from 0.21 to 420 μ M. Imidocarb dipropionate was used as a positive control. The plates were incubated for 24h at 37°C in a CO₂ atmosphere (5%); the parasitemias corresponding to each dilution were evaluated by fluorometry²⁰, and the IC₅₀ was determined by a regression model.

Anti-trypanosoma activity

Trypanosoma congolense IL3000 bloodstream forms and *Trypanosoma brucei brucei* Antat

1.1 bloodstream forms were cultured with 100 µl in complete MEM and IMDM culture medium respectively at 25×10^3 cells in 96-well plates for 24h at 34°C and 37°C respectively with 5% CO₂. Alsinol assays were performed with 150 µl of Alsinol solution at 10 µg/ml in 0.1% DMSO. Three controls were included: a trypanocidal control with 150 µl of Diminazene aceturate at 1.5 µg/ml, a negative control without a drug and a 0.1% DMSO control. All assays were performed three times in triplicate. After 24h, parasite proliferation was determined using the Malassez cell numeration.

Anti-leishmania activity

Parasites of *Leishmania infantum* transfected with luciferase gene were maintained at 24°C in RPMI 1640 medium containing 10% heat-inactivated fetal bovine serum. Parasites were harvested by centrifugation (900 g, 10 min) and washed two times in NaCl 0,9%, re-suspended in medium and distributed in a 24-well plate. For the determination of anti promastigote activity, Alsinol was incorporated in the medium at growing concentrations. The Luciferase enzyme present in *Leishmania infantum* transfected with luciferase gene converts a substrate D-luciferase + ATP to a reaction product (oxyluciferin, excited state) that emits photons which are measured with a luminometer; therefore the amount of ATP is directly proportional to the number of live parasites present in each well.

Toxicity

The assay was adapted from Cachet et al.²¹ using normal monkey kidney cells (Vero cells) under the similar *P. falciparum* culture conditions, except that human serum was changed to 10% fetal calf serum. After the addition of Alsinol at increasing concentrations, cell growth was measured by [3H]-hypoxanthine incorporation after a 48h incubation period and then compared with a control sample. Doxorubicin and amphotericin B were used as controls.

Macrophages murine J774 A.1 were maintained at 37°C in RPMI 1640 culture medium supplemented with 10% heat-inactivated fetal bovine serum; cultures were allowed to 70-80% confluent and cells were gently scraped. Cells were diluted in culture medium to 10^6 cells/ml final concentrations and distributed into a 24-well plate and incubated for 24h. The activity of

Alsinol was determined by an MTT colorimetric assay (Eon Microplate Spectrophotometer Gen5™ v 2.0 at 570nm). Miltefosine, doxorubicin and amphotericin B were used as control drugs.

Alsinol was also tested on HepG-2 cells. Chloroquine was used as a control drug.

In vivo studies

Antimalarial

Studies were carried out in accordance with Colombian legislation on the use and care of laboratory animals (N° 008430) and approved by the Faculty of Science Ethics Committee (Dec 04-2017). Swiss mice (5 to 6 weeks-old) were obtained from the Bioterium Pharmacy Department, *Universidad Nacional de Colombia* and housed at 18°C in a 12h light/dark cycle, with free access to commercial food pellets and water. *Plasmodium berghei* ANKA parasites were maintained by weekly passage of infected blood to the Swiss mice.

Blood schizontocidal activity on *P. berghei* was determined through a variation of the experimental design of the 4-day test of Peters & Robinson,²² adapted by Garavito.²³ Compounds were tested by oral route to establish ED₅₀ and ED₉₀ values.²⁴ Mice were randomly assigned into groups of five and were infected intraperitoneally with 0.1 ml containing 10⁷ parasitized cells, from a donor mouse (day 0). After two hours of infection and at the same time for four consecutive days (D0 to D+3), the mice were then orally dosed with Alsinol (dose-ranging 6.25-50 mg/kg/day).⁸ Chloroquine diphosphate (CQ), dose-ranging 1.5-12 mg/kg/day, was used as a control drug. A group received the vehicle of treatments (90% DMSO/water solution). Survival of the mice was checked daily and the percentage of parasitized erythrocytes was determined on D+4, with SYBR green I as described previously.²⁵ The percentage of inhibition of parasitemia was calculated and ED₅₀ and ED₉₀ were determined by a regression model.

Trypanocidal

All procedures for animal maintenance and experimental procedures were approved by the Languedoc-Roussillon regional ethics committee (French CE-LR #36) in the authorized Project using animals for scientific purposes #C34-172-20. Eight groups of 5 Balb/C mice, aged 6 weeks, were used for *in vivo* assays. Four assays groups were designed with an infected group, infected/Alsinol group, infected/Diminazene aceturate group, and infected/DMSO group. Five control groups were included with negative control, infected control, DMSO control, Alsinol control and Diminazene aceturate control.

Mice infection was performed by intraperitoneal (IP) injection with 10^4 of *Trypanosoma congolense* IL1180 diluted in 1% salt glucose solution. The weight of the mice and their anemia (PCV packed cell volume) estimation were measured before infection, during infection and at the end of the experimental procedure. As soon as parasites were detectable under microscope observation, the mice were treated by IP injection with 200 μ l of Alsinol at 2 mg/ml or with Diminazene aceturate at 3.5mg/kg or with 4% DMSO. The same treatment was performed for control groups. Parasitemia was determined daily by blood collection from the tails of the mice by field method estimation; survival at D+9 was determined.²⁶

Results

Chemistry

Structure

The synthesized final Alsinol was chemically characterized by melting point (mp) and proton and carbon nuclear magnetic resonance (^1H NMR and ^{13}C NMR) spectra as well as by elemental microanalysis: Yield: 11%, mp 185-187 °C, ^1H NMR (400 MHz, DMSO- d_6) δ : 8.37 (brs, 2H), 7.50 (d, 1H, J = 8.0 Hz), 7.36 (br s, 2H), 7.13 (t, 2H, J = 8.1 Hz), 5.61 (s, 1H); 4.69 (t, 1H, J = 9.0 Hz), 3.20-3.30 (m, 2H), 2.95 (t, 2H, J = 12.1 Hz), 2.63-2.64 (m, 2H), 2.58 (br s, 1H), 1.90 (d, 2H, J = 11.0 Hz), 1.70 (br s, 2H), 1.38 (br s, 2H) ppm. ^{13}C NMR (DMSO- d_6 , 100 MHz) δ : 163.06; 160.66; 157.70; 143.19 (d, J = 2.7 Hz); 141.73; 129.21; 128.34 (2C,

d, $J = 8.0$ Hz); 124.98 (q, $J = 6.0$ Hz); 123.88; 122.82; 115.49 (2C, d, $J = 21.1$ Hz); 71.59; 54.24; 52.08 (2C); 44.00; 35.62; 32.34 (2C) ppm. Anal. Calcd for $C_{21}H_{23}N_3F_4O_3 \cdot HCl$: C, 52.51%; H, 5.03%; N, 8.80%; Found: C, 52.13%; H, 4.91%; N, 8.49%.

In silico

Physicochemical properties (ADME profile).

Chemical descriptors and physico-chemical properties of Alsinol are reported in Table 1.

Table 1: Physical chemical properties of Alsinol and chloroquine, Lipinski's rules²⁷ and Ghose "qualifying range"²⁸.

Properties	Lipinski's rule ²⁷ (Ghose's rule) ²⁸	Alsinol	Chloroquine
Molecular weight	>500 (160-480)	441	320
CLOGP	<5 (-0.4-5.6)	3.84	4.63
NH- or OH- bond donors	≤5	2	1
H- bond acceptors	≤10	6	3
Total number of atoms	(20-70)	54	48
n-ROTB	≤10	7	8
Polar surface area	< 140 Å ²	81.3	28.2

%ABS: human intestinal absorption, calculated by: %ABS=109-(0.345 x Topological Polar Surface Area). Hydrophilicity: LogD (pH:7.4)/logP.

Alsinol passed the first in silico screen of Lilly OIDD. This means that it was considered that it does not generate interference with assay measurements (fluorescence, absorbance, quenching), it does not have activities that damage proteins (oxidizers, detergents), has no instability (e.g., latent aldehydes), does not lack druggability (e.g., compounds lacking both oxygen and nitrogen), it has an acceptable index of biological promiscuity.¹²

Bioactivities

In vitro

In vitro results against Plasmodium, Babesia, Trypanosoma and Leishmania are displayed in Table 2. Alsinol showed schizontocidal activity against *P. falciparum* in culture ranging from around 0.48 on FCR-3 and D6 strains to 1.05 on the C235 strain (previously reported data^{6,8}). Against late stage gametocytes of *P. falciparum*, Alsinol inhibits parasites preferentially in their mature sexual stage following a dose-dependent scheme (Figure 3). Cultures treated with Alsinol and primaquine produced fewer gametocytes than the control ($p < 0.05$, Tukey post-hoc test). The active control drug (PQ), at 22 μM , generated a total inhibition of gametocytogenesis.

Figure 3. Inhibition of sexual stages of *P. Falciparum* W2 by Alsinol.

Gametocytogenesis inhibition (dotted line) and gametocide effect (plain line). The effect of primaquine is visualised with crosses.

Against *B. divergens*, Alsinol shows concentration-dependent inhibition (Figure 4), with IC_{50} being an order of magnitude greater than that of the active control drug, Table 2. Cultures treated with Alsinol (52 and 26 μM) and ID (200, 20 and 2 μM) produced fewer parasites than the control untreated cultures ($p < 0.05$ in each case, Tukey post-hoc test).

Alsinol inhibited 100% of *Trypanosoma b. brucei* and *Trypanosoma congolense* growth at 21 μM .

Figure 4. Growth inhibition of *Babesia divergens* (Alsinol plain line, Imidocarb propionate dotted line).

Alsinol was also active against *Leishmania infantum* promastigote and amastigote forms inhibiting 50% of parasite growth at around 2 and 8 μM respectively.

The cytotoxicity of Alsinol was also determined on Vero cells, macrophage-like murine cells J774A.1, and on Hep-G2 cells. The CC_{50} was 30 μM on Vero cells, 8.2 on J774 and 10.4 on Hep-G2.

Table 2. *In vitro* and *in vivo* bioactivity of Alsinol, Chloroquine, Primaquine, Imidocarb, Diminazene aceturate, Miltefosine, Amphotericin B and doxorubicine.

Assay	ASN	PQ	CQ	ID	DA	MIL	AmphoB	Doxo
<i>IN VITRO</i> (IC ₅₀ or CC ₅₀ µM)

<i>T. congolense</i>	Inactive				80% survival			

ASN: Alsinol, CQ: chloroquine, PQ: Primaquine, ID: Imidocarb, DA: Diminazene aceturate, MIL: Miltefosine, AmphoB: amphotericin B, Doxo: doxorubicine. IC₅₀ Concentration inhibiting 50% of parasite growth. IC₉₀ Concentration inhibiting 90% of parasite growth. CC₅₀ Concentration killing 50% of cells. ED₅₀ Dose inhibiting 50% of parasite *in vivo*. ED₉₀ Dose inhibiting 90% of the parasite *in vivo*. *% Inhibition at 22 μ M. **% Inhibition at 21 μ M.

In vivo

Plasmodium infected animals treated with Alsinol (50 and 25 mg/kg/day) and CQ (12.6 and 3 mg/kg/day) showed fewer parasites than untreated animals ($p < 0.05$ in each case, Tukey post-hoc test) see Table 2 and Figure 5. Chloroquine had an effective doses 50 (ED₅₀) of 2.4 mg/kg/day, consistent with the ED₅₀ of 2.2 mg/kg/day and 2.3 mg/kg/day previously reported by our team,^{25,29} while Alsinol exhibited ED₅₀=17.4 and ED₉₀=48 mg/Kg/day.

Against *Trypanosoma congolense* IL1180 (reference strain for experimental infection as it is less virulent than IL3000 enabling the infection to be monitored). Alsinol did not show activity in our model.

Figure 5. Alsinol antimalarial activity against *P. berghei* ANKA (Alsinol plain line, Chloroquine dotted line).

Discussion

Vector-transmitted infectious diseases are a serious problem for human and animal health in tropical and subtropical regions of the world, affecting more than 500 million people, accounting for 16% of all communicable human diseases. In developed countries, their morbidity and mortality are increasing as a consequence of human migration, changes in the geographical distribution of vectors and the emergence of resistance to infectious agents.^{30–33}

The control of parasitic diseases is essential to achieve several of the United Nations Sustainable Development Goals.³⁴

In the parasitic disease register, malaria is claimed to be responsible for more than 200 million cases and almost 500,000 deaths, with nearly half of the world's population at risk. Although the overall downward trend has undoubtedly stabilized and, in some areas, a decrease is becoming evident, according to WHO³⁵, the fight against malaria still requires increased funding for control programs, greater access to effective interventions and investment in research and development of new tools.

In recent years, strategies to optimize existing antimalarial therapies focused on the use of combination therapies, the reuse of drugs in other indications and/or the use of natural products.^{33,36–39} In parallel, chemists all around the world still continue with the synthesis of potentially effective drugs structurally similar to existing drugs. This is what our team did by way of exploring the structure-activity relationship of γ -aminoalcohols and more specifically, the 1-aryl-3-substituted derivatives of propanol.^{6–9} The *in vivo* screening of the most promising compounds against *P. berghei* rodent malaria, revealed that the central amine influences the activity as seen with aminopiperidine analogues that are more active than piperazine analogues. Although compound “22” (Table 3) showed an excellent reduction of parasitemia, it had low *in vitro* selectivity index (SI=37) and was discarded. Then, Alsinol was selected to be studied further.

Table 3. *In vivo* antimalarial efficacy of selected compounds in *P. berghei*-infected mice.

Compound	Ar	Amine	R ₁	R ₂	% Suppression of parasitemia
22			CF ₃	NO ₂	98 ± 1
23			H	F	73 ± 16
24			CF ₃	NO ₂	17 ± 8
Alsinol			CF ₃	NO ₂	76 ± 30
CQ					87 ± 11

Compounds were evaluated at an oral dose of 50mg/kg x 4 days. CQ: Chloroquine. Adapted from Quiliano et al.⁸

Chemistry

Alsinol is easily synthesized in 4 steps at a low cost leading to a mixture of enantiomer.⁸ There were no significant potency differences between enantiomers and the racemic mixture against *P. falciparum* F32 Tanzania, chloroquine sensitive strain (F32 IC₅₀=0.5μM) (data not shown). Consequently, there is no need to separate the enantiomers to enhance the bio-activity.

Alsinol has a calculated n-octanol/water partition coefficient (CLOGP $\log(\text{n-octanol/water})$) of 3.84; when this coefficient is estimated at pH 7.4 (at protonated form (>99%)) the value diminishes to 1.51 in increasing its hydrophilicity. A hydrophilic compound is normally well absorbed, even if it has a moderate or low permeation rate; problems in the absorption of a drug can derive from a low aqueous solubility since the flow of a molecule, through the intestinal membrane, is proportional to its concentration gradient between the intestinal lumen and the blood. It is noteworthy that the LogD (pH 7.4)/logP coefficient is 0.39 for Alsinol, which could be used as a measurable approach of hydrophobicity.

In the research and development of new drugs “Lipinski’s rule of 5” helps to estimate poor absorption or permeation of a new molecule, that is more probable if there are more than 5 H-bond donors, more than 10 H-bond acceptors, molecular weight greater than 500 and calculated Log P (CLogP) greater than 5.²⁷ A molecule should not violate more than one of Lipinski’s considerations for oral administration to be feasible. Also inside the Ghose²⁸ “qualifying range” for drug-like molecules, the chance of missing good compounds is less than 20%. Alsinol respects Lipinski’s rules and the Ghose qualifying range, Table 1.

Earlier, our team reported a computational study, performed for the prediction of the ADME profile of Alsinol in order to evaluate its drug likeness, in that, Alsinol exhibited an oral bioavailability of 81% (%ABS) , considered interesting as an agent for antimalarial therapy.⁸ Alsinol shows less than 10 rotatable bonds estimating a high probability of good oral bioavailability.⁴⁰

In a previous structure-activity relationship we demonstrated that the incorporation of a single fluorine atom in the Ar (hydrophobic) region provided potency and that if the –F was moved from para to ortho position, it resulted in a drop of the bioactivity. The central amine also influences the activity. This finding is in agreement with the results reported by Molyneaux et al.⁴¹ that show unsubstituted amines (free NH) have significant antiplasmodial activity in resistant strains compared to their substituted analogues. One feasible explanation is that unsubstituted nitrogen (NH) may interact easily with possible targets, as there is a greater

hydrogen bond capacity.

The arylamino alcohol (β -amino or γ -amino alcohol moiety) is the classic antimalarial chemotype present in some antimalarial drugs, including quinine, mefloquine, lumefantrine, and halofantrine. The structural requirements for antiplasmodial activity include an aromatic and amino alcohol portion linked by a carbon chain of two or three atoms in length.⁴² Moreover, it has been shown that mefloquine presents some activity against *Babesia*, *Trypanosoma* and also *Leishmania*.⁴³ This is the reason why we also decided to determine the activity of Alsinol against these parasites.

Antimalarial activity

The *in vitro* schizontocidal activity of Alsinol has been assessed against chloroquine-sensitive and resistant strains of *P. falciparum* (NF-54/D6 and FCR-3/C235, respectively). Alsinol was as active as the control on the FCR-3 strain ($IC_{50}CQ = 0.13 \mu M$) while compared to the C235 strain ($IC_{50}CQ = 0.048 \mu M$) the activity was two orders of magnitude lower. On synthesized strains ($IC_{50}CQ$ NF-54 = $0.04 \mu M$, D6 = $0.014 \mu M$) IC_{50} of Alsinol was 2 and 1 order of magnitude higher respectively.

The resistance index (IC_{50} resistant strain / IC_{50} sensitive strain) was <1 against NF-54, i.e., Alsinol was more active against the resistant strain than against chloroquine-sensitive strains NF-54, showing a typical "mefloquine behavior".⁶ The index was ≥ 1 against D6, i.e., Alsinol being as or less active against resistant strains (Table 4).

Table 4. Resistance index of Alsinol against multidrug-resistant and chloroquine sensible strains.

Strain	$IC_{50} \mu M$	NF-54	D6
$IC_{50} \mu M$		1.3	0.49
FCR-3	0.48	0.4	1.0
C235	1.05	0.8	2.1

IC₅₀: growth inhibition of 50% of parasite. FCR-3 and C235 *P. falciparum* multidrug-resistant strains. NF-54 and D6 *P. falciparum* chloroquine sensible strains. Resistance index: IC₅₀resistant strain / IC₅₀sensitive strain. Dark cells: calculated data. Clear cells: previously reported data.^{6,8}

The gametocyst stages of *P. falciparum*, when mature (10 and 14 days after the first appearance in blood of the asexual forms), are required for transmission of the disease by the mosquito vector. The process leading to the passage of asexual erythrocytic forms to sexual forms is called gametogenesis and represents a transition period in which the parasite is morphologically and biochemically differentiated, preparing the passage to the mosquito.

Although asexual blood forms and immature gametocytes share metabolic profiles (i.e., digestion of hemoglobin), being vulnerable to drugs that act on those metabolic pathways, this situation changes with the mature stages of the gametocytes (stages IV and V) that are relatively insensitive to most current drugs, except primaquine.⁴⁴ In our hands against the gametocysts stages, the reference drug (primaquine) showed activity similar to that reported by Sall et al.⁴⁵ and Chevalley et al.,¹⁷ inhibiting 75% of gametocytes viability and 100% of gametocytogenesis at 22μM. Alsinol inhibited 50% of gametocyte viability and gametocytogenesis at 1.23μM and 3.75μM respectively. Figure 3 shows clearly that Alsinol is in the range of activity of primaquine. This remarkable biological activity of Alsinol makes it a potential tool for the control and elimination of malaria, capable of eliminating sexual forms of the parasite, thus blocking the disease transmission cycle.³

Working with potential metabolites,⁸ we deduced that antimalarial activity of Alsinol was related to the entire molecule and not to the amine scaffold intermediate.

The *in vivo* assessment of the blood schizontocidal activity showed dose-dependent behavior of Alsinol against *P. berghei* (Figure 5). In a previous report, Alsinol at 10 mg/kg/day inhibited 35% of parasite growth,⁶ while in another study it inhibited 76% of parasite growth at 50 mg/kg/day.⁸ In our hands Alsinol inhibited 26% and 100% of parasite growth at 12.5

and 50 mg/kg/day respectively. We showed here that it had an ED₅₀ (17.4 mg/kg/day) around 7 times higher than CQ (2.4 mg/kg/day), with a highly promising ASN in a very demanding preclinical animal model of infection and using an oral route as the way of administration. This condition involves not only the biological inherent response of a complete organism but also the pharmacokinetics challenges to be overcome by a drug that can be administered in the most recommended way for clinical use. All these experiments were conducted with different product batches, demonstrating correlation in the biological activity of different batches of synthesis of the molecule evidencing reproducibility in the process of obtaining ASN.

In an attempt to get further insight on the mechanism of actions, Alsinol was tested on the hemozoin formation drug target pathway, against plasmepsin⁸ and Hsp90 chaperone. Alsinol was ineffective against all these targets. Alsinol exhibits a mechanism of action different from classical amino alcohols.⁹

Anti-Babesia activity

Babesia is a tick-borne disease affecting many species of vertebrates, including humans, but it is mostly known because of its role in economic losses in cattle due to decreased milk or meat production, abortions and mortality. The disease causes huge economic losses in cattle, especially in Latin America where it is claimed to reach US 1,365 million/ year.⁴⁶⁻⁴⁸

The disease cycle takes place in red blood cells in vertebrate hosts, like *Plasmodium*. Consequently, peripheral smears of babesiosis can be easily confused with the malaria parasite and mistreated. The human infection causes mild malaria-like fever, but it could be life-threatening in immune-compromised people and people receiving blood transfusion. Its importance in humans has been reported due to the rapid increase in case reports worldwide.^{49,50} Nevertheless, as the disease is unknown to many clinicians, there is certainly high under-reporting of the number of cases.

The drugs of choice for the treatment of animal babesiosis are imidocarb dipropionate and diminazene acetate, but the latter was withdrawn from the market in Japan and its use is not approved by the U.S. Food and Drug Administration, due to its high toxicity.⁵¹ The usefulness of antimalarial drugs against different protozoan parasites is currently the subject of intense research.⁵² *In vitro* artesunate (AS), pyrimethamine and pamaquine completely inhibit the growth of *Babesia equi* (now *T. equi*) and *B. caballi*.^{53,54} Interestingly, it has been shown that artemisone inhibits parasitic growth, reduces clinical symptoms and promotes the recovery of cattle infected with *B. bovis* and *B. bigemina* without complete elimination of the parasite, which is a desirable effect as it allows animals to develop relative immunity by pre-munition reducing the severity of the disease from future infections.⁵⁵ Artesunate inhibits the parasitic growth of *B. bovis* and *B. gibsoni* and does not allow re-emergence upon withdrawal of treatment.⁵¹ Artemisone inhibits the parasitic growth of *B. bovis* and *B. bigemina*, *B. bigemina* being more sensitive to its pharmacological action.⁵⁵ Chloroquine showed a more potent babesicidal activity against *B. divergensis* than diminazene acetate;⁵⁶ *In vivo*, artesunate, atovaquone and primaquine inhibited parasitic growth in *B. microti*-infected mice, without complete elimination of parasites and without producing side effects in experimental animals.^{51,57} Yokoyama et al.,⁵⁸ showed that *Babesia* was sensitive to mefloquine *in vitro* with IC₅₀ ranging from 4μM to 60μM according to the species used. It was also active against *B. microti* in mice at 5mg/Kg by IP route. It is interesting to note that other authors also showed that sensitivity to drugs varies according to strains and species.^{59,60}

Human disease is treated with a combination of quinine + clindamycin or atovaquone + azithromycin (and in some extreme cases exchange transfusion) with frequent adverse effects and recent reports of treatment resistance.⁶¹

In our hands *in vitro* Alsinol had an IC₅₀ 10 times higher than the control drug Imidocarb dipropionate. Interestingly it had an IC₉₀ only 3 times greater than imidocarb, showing promissory activity against the most pathogenic agent of human and bovine babesiosis, Table 2, Figure. 4.

Anti-Trypanosoma activity

African trypanosomiasis is a parasitic disease affecting humans and other animals in 36 sub-Saharan African countries. It is a vector-borne parasitic disease transmitted by tse-tse flies and caused, in humans, by *Trypanosoma brucei gambiense* (west Africa) and *T. brucei rhodesiense* (eastern and southern Africa). The human form is commonly known as ‘sleeping sickness’.

In sub-Saharan Africa *T. congolense*, *vivax* and *brucei brucei* are responsible for the most important vector-borne livestock disease with dramatic impact on nutritional security ⁶².

The drugs available for African sleeping sickness are pentamidine isethionate, suramin, melarsoprol, eflornithine, or nifurtimox–eflornithine combination treatment. The currently available trypanocidal drugs are associated with side effects, and the parasites are continually developing resistance. Interestingly Otigbuo and Onabanjo⁶³ showed that mefloquine was able to inhibit the multiplication of the parasites *in vitro* but was also able to clear infected mice after administration of 0.03 mg/kg for 4 consecutive days. Nevertheless, to the best of our knowledge, mefloquine has not been prescribed for humans so far. Only 3 molecules are available in veterinarian medicine (diminazene diacetate, isometamidium chloride hydrochloride, homidium). Resistance has been documented^{64,65} due to low quality and inadequate uses. In our hands, Alsinol was able to inhibit parasite growth *in vitro* but unfortunately, not *in vivo*.

Leishmanicidal activity

The leishmaniasis are a group of zoonotic diseases caused by protozoa of the genus *Leishmania* transmitted to humans by phlebotomine sandflies. In humans when inoculated by the vector, promastigotes are rapidly transformed into amastigotes, which actively divide

within the mononuclear phagocytes of the vertebrate host. More than 300 million people are living in endemic tropical and subtropical areas, 2 million are infected and 30,000 die annually, mainly among the poorest, malnourished part of the population with limited access to health services. Three clinical forms have been described: cutaneous leishmaniasis, mucocutaneous leishmaniasis, and visceral leishmaniasis.

Current anti-leishmanial drugs include pentavalent antimony (the first-choice treatment for both visceral and cutaneous leishmaniasis), amphotericin B and pentamidine (second-line antileishmanial drugs), paromomycin and miltefosine. They have all dramatic toxic effects on liver, heart and kidney, and are also responsible for a long list of side effects (anaemia, fever, anorexia, vomiting, nausea, abdominal pain, malaise, myalgia, arthralgia). Therefore, usage is limited by their toxicity and adverse reactions. Moreover, some of them require hospital settings and long-term administration, up to one month in the case of visceral leishmaniasis. All these factors contribute to the interruption of treatment, increasing the emergence of resistance to drugs. Many studies have been run with artemisinin and derivatives against *Leishmania*. Although results obtained in laboratories were positive, they were not consistent for introduction with human therapeutic strategies. Mefloquine has been shown to be effective against promastigotes in axenic cultures and showed an IC_{50} of $8.4 \pm 0.7 \mu M$. Besides, mefloquine, chloroquine and hydroxychloroquine were active against intracellular amastigotes in macrophage-infected cultures, with IC_{50} values of $1.56 \pm 0.19 \mu M$, $0.78 \pm 0.08 \mu M$ and $0.67 \pm 0.12 \mu M$, respectively.⁴³

In our hands, Alsinol was almost 4 times more active than miltefosine but 66 times less active than amphotericin B on promastigotes of *Leishmania* (the form found in the vector). On amastigotes it was 2 times less active than miltefosine but more than 130 times less active than amphotericin B.

Toxicity

Alsinol on HepG-2 had a selectivity index of 22. Moreover, genotoxicity profiles of potential

metabolites were not considered genotoxic using the SOS/umu test.⁸ Toxicity on Vero cells (CC₅₀ 30µM) showed that Alsinol had a Selectivity index of 60 compared with activity on *P. falciparum* (FCR-3 and D6) *in vitro*, one compared with activity on *Babesia divergens in vitro*, 15 compared with activity on *L. infantum* promastigotes *in vitro* and only 3.75 compared with activity on *L. infantum* amastigotes *in vitro*.

It was therefore 4 times less toxic than amphotericin B and 130 times less toxic than doxorubicine on macrophage-like cells J774A1. On Vero cells, it was 4 times less toxic than doxorubicine and amphotericin B.

Conclusions

All of humanity is affected by parasites. Unfortunately, the search for new therapeutic alternatives is not a priority of the Pharmaceutical industry as most affected people live in extreme poverty and cannot afford the price of medicines. The role of public research is then to counterbalance this situation in order to propose antiparasitic drugs that are effective, safe and easy to use at low cost.

The usefulness of antimalarial drugs against different protozoan parasites is currently the subject of intense research.

We showed that Alsinol is a potent antiplasmodial agent against both sexual and asexual stages of *P. falciparum*. The remarkable biological activity of Alsinol makes it a potential tool for the control and elimination of malaria, capable of eliminating sexual forms of the parasite, thus blocking the disease transmission cycle.

Alsinol evidences concordance between the results of *in vitro* studies, with *in vivo* valuations in a demanding pharmacological model that involves both the different variables that affect the biological response to an anti-infective agent (non-specific immune response, residual effect) and the pharmacokinetic variables derived from oral administration, the most recommended for clinical use in this group of drugs.

There is an alarming lack of new promising antimalarial hits and a shortage in the production of affordable drugs worldwide. Therefore it could be expected that Alsinol could satisfy this high demand and be a low cost-efficient alternative to avoid a shortcut to the millions of treatments needed to save lives.

In the same way, babesiosis is causing economic losses in cattle-production systems worldwide. This disease contributes to poverty in Southern countries and also has a huge impact on the North. There is no affordable and effective treatment so far. The economic impact is particularly heavy and can be expressed in terms of mortality, loss of production (weight, milk production, skin), and the cost of control. Our findings also show the promising activity of Alsinol against the most pathogenic agent of human and bovine babesiosis.

Nevertheless, although Alsinol showed some activity against African trypanosomoses, it was ineffective *in vivo*. This point could be circumvented through suitable galenic formulation but further studies are necessary, including toxicity. It is also important to scale up the production of Alsinol to get sufficient amount of Alsinol for industrial requirements.

Acknowledgments

We wish to thank Michael Browne for editing the document.

Alsinol is a drug designed thanks to a straight collaboration between UMR152 IRD-UPS and the Universidad de Navarra (*Unidad de Investigación y Desarrollo de Medicamentos*). It was supported by the *Direction de la Valorisation au Sud* (DVS) in the frame of the IRD Maturation projects programme. This study was funded by the *Departamento Administrativo de Ciencia, Tecnología e Innovación (Colciencias)* and the French Ministère des Affaires étrangères et du Développement international (MAEE) through ECOSNORD 2013 program [HERMES- 28693] and the *Vicedecanatura de Investigación, Facultad de Ciencias, Universidad Nacional de Colombia*. This work was supported by PIUNA Project-University of Navarra and Foundation CAN (grant number: 70391). The authors are grateful to the Institute of Tropical Health (ISTUN) of University of Navarra for the financial support and

help. They also acknowledge the support of *Laboratoire d'Excellence (Labex)* Parafrap N8ANR-11-LABX-0024. MH Arias is grateful to *Departamento Administrativo de Ciencia, Tecnología e Innovación (Colciencias)* for their Ph.D. scholarship (*Convocatoria 647, Doctorados Nacionales 2014*), M Quiliano is grateful to “*Programa Nacional de Innovación para la competitividad y productividad*” (Innóvate-Perú) for his PhD scholarship (grant 065-FINCYT-BDE-2014). A Mendoza acknowledges ADA (University of Navarra) for a PhD scholarship. The authors thank MF Richards for critical reading of this manuscript.
