ARTICLE

Aerobic Oxidation Catalyzed by Polyoxometalates Associated to an Artificial Reductase at Room Temperature and in Water

Ahmad Naim,^{a,b} Yoan Chevalier,^a Younes Bouzidi,^a Priyanka Gairola,^{a,b} Pierre Mialane,^{b*} Anne Dolbecq,^b Frédéric Avenier,^{a*} Jean-Pierre Mahy^a

Four polyoxometalates (POMs) were combined with an artificial reductase based on polyethyleneimine (PEI) and flavin mononucleotide (FMN) which is capable of delivering single electrons upon addition of nicotinamide adenine dinucleotide (NADH). The efficiency of this system for sulfoxidation reactions in water, at room temperature, under atmospheric pressure and with dioxygen as an oxidant was demonstrated, with yields up to 82% in sulfoxide. Mechanistic investigations allowed proposing two different catalytic pathways, depending on the nature of the POM. For the polyoxotungstates $\text{Na}_{12}[(\text{ZnW}_9\text{O}_{34})_2\text{WZn}_3(\text{H}_2\text{O})_2]\cdot 46\text{H}_2\text{O}$ and $\text{Na}_7\text{K}_7[\{(\text{PW}_9\text{O}_{34})\text{Ni}_3(\text{OH})(\text{H}_2\text{O})_2(\text{Ale})\}_2\text{Ni}]\cdot 34\text{H}_2\text{O}$ (Ale = alendronate = $[\text{O}_3\text{PC}(\text{O})(\text{C}_3\text{H}_6\text{NH}_3)\text{PO}_3]^{4-}$), the *in situ* production of H_2O_2 by the artificial reductase that activates the POM was evidenced. Alternatively, for the polyoxomolybdates $\text{H}_3[\text{PMo}_{12}\text{O}_{40}]\cdot 14\text{H}_2\text{O}$ and $\text{H}_4[\text{PMo}_{11}\text{VO}_{40}]\cdot 14\text{H}_2\text{O}$, the reduction of the POM by the artificial reductase, followed by the reductive activation of O_2 , led to the sulfoxidation reaction.

Introduction

The majority of industrial chemical processes, such as oxidations, are based on harsh conditions (high temperature, pressure, corrosive oxidants and/or toxic solvents), leading to a harmful impact on the environment.¹ It has therefore become essential, in the present context of sustainable growth, to develop new environmentally friendly chemical processes.^{2–7} There are different manners to reduce the impact of chemical processes on the environment and at least two key points have to be addressed: (i) to reduce energy consumption by lowering temperature and pressure, (ii) to reduce waste production by avoiding organic solvents and by improving the selectivity and the chemical yields. On the one hand, enzymes entirely fulfill these requirements, but unfortunately also require numerous steps of cloning, over-expression and purification, which strongly restricts their use in industrial processes.⁸ On the other hand, many of the chemical processes that are usually used are based on potentially harmful catalysts to the environment.⁹ Therefore, the development of bio-inspired catalysts, mimicking enzymes activity, is a major challenge in order to take advantage of both enzyme specificity and robustness of handmade catalysts.^{10,11}

Sulfoxidation is one of the most fundamental chemical reaction in organic synthesis as, for example, many sulfoxides and sulfones

intermediates have been shown to be the active principals of several drugs.¹² The oxidation of a sulfide (thioether) molecule can yield sulfoxide and/or sulfone products depending on the applied oxidation method,¹³ and many reagents are able to selectively form sulfoxide and/or sulfone adducts. However, they are usually based on toxic and corrosive oxidants such as peroxides, peracids, halogen or nitrogen-oxide derivatives.^{13–15} The main challenge is now to use dioxygen which represents a cheap, clean and readily available oxidant, notably used in nature by enzymes that perform oxidation reactions in aqueous solution and under mild conditions. In this respect, many catalytic oxidation reactions exist in the literature using dioxygen, but most of them use harmful catalysts and organic solvents under harsh conditions (high temperature or pressure).^{16–21} In contrast, nature has figured out an elegant manner to catalyze such reactions by reductive activation of molecular dioxygen. As a typical example, O_2 reduction activation occurs at iron(II) centers present in multi-component enzymatic systems named iron monooxygenases.^{22–24} It should be underlined that while monooxygenases such as cytochromes P450 are able to activate dioxygen in order to selectively oxidize alkanes into alcohols, they require a steady and accurate input of electrons. These electrons are provided by an associated reductase, a flavoprotein that collects electron pairs from nicotinamide adenine dinucleotide (NADH) or nicotinamide adenine dinucleotide phosphate (NADPH) and delivers a single electron flow to the metallic active site of the enzyme thanks to its flavin adenine dinucleotide (FAD) and flavin mononucleotide (FMN) cofactors. The reductive activation of dioxygen at the iron center allows the formation of high-valent iron-oxo species capable of transferring an oxygen atom into the C-H bond of diverse substrates.^{25–27} Many efforts have been made to mimic flavoenzymes^{28–31} in order to deliver electrons accurately to metal catalysts but it has been proven very difficult to combine

*Electronic Supplementary Information (ESI) available: detailed synthetic procedures, representation of the POMs and additional spectroscopic characterizations. See DOI: 10.1039/x0xx00000x

these reductive conditions with the formation of high valent iron-oxo species.³² Consequently, most of the bio-inspired systems developed so far shunt this reduction process by the use of hydrogen peroxide.^{33–36} Also, the majority of other bio-inspired systems that are based on FMN have employed H₂O₂ as oxidant to catalyze the oxidation of sulfides^{37–44} or amines^{45,46} and Baeyer-Villiger reactions.^{47,48} Recently, we developed an artificial enzyme by incorporating FMN inside a water soluble polyethyleneimine polymer functionalized with guanidinium and octyl groups (PEI_{guan-oct}), and we demonstrated that NADH could reduce FMN into FMNH₂ which was then able to deliver a single electron flow to redox cofactors (Scheme 1) such as manganese porphyrins⁴⁹ or copper complexes.⁵⁰ This artificial reductase (FMN-PEI_{guan-oct}) was capable of reducing a functionalized Mn(III)-porphyrin that could then react with dioxygen in order to perform thioanisole oxidation, in low yields. In order to improve the catalytic efficiency of this system, we decided to replace the metalloporphyrin catalyst by polyoxometalates (POMs), a family of tunable, highly water-soluble and efficient catalysts for oxidation reactions.^{51–53} Although it has been shown that POMs could activate dioxygen,^{54,55} very few studies dedicated to oxidation catalysis in water-containing media have been reported so far. However, it is known that in acetic acid/water mixtures H_{3+x}PV_xMo_{12-x}O₄₀ (x = 1–6) can act as co-catalyst in several Pd^{II} catalysed reactions.⁵⁶ Also, in the same media, it has been shown that H_{3+x}PV_xMo_{12-x}O₄₀ could oxidize cyclohexanone in presence of O₂ (T = 70°C).⁵⁷ Besides, it has been evidenced that when incorporated into a cationic polyethyleneimine-based polymer, the [(ZnW₉O₃₄)₂WZn₃(H₂O)₂]¹²⁻ POM was capable of catalyzing the oxidation of sulfides and alkenes in water. Nonetheless, this system required hydrogen peroxide as oxidant.³³ Thus, POM-incorporating oxidative catalytic systems, working in pure water, at room temperature and with dioxygen as oxidant under atmospheric pressure, remain to be developed. Herein, we report for the first time a system where polyoxometalate catalysts have been combined in solution with an artificial reductase (FMN-PEI_{guan-oct}) in the presence of NADH as a source of electrons for the reductive activation of dioxygen. Four different POMs, including two polyoxotungstates and two polyoxomolybdates, have been selected. The catalytic activity for the aerobic sulfoxidation reaction of the elaborated systems was studied, and the involved mechanisms were investigated.

Scheme 1. Schematic representation of an artificial flavo-reductase (FMN-PEI_{guan-oct}) made of FMN incorporated into a water-soluble PEI modified with guanidinium and octyl groups.

Experimental

The series of water soluble Keggin type polyoxometalates based on low-toxic non-noble metals, namely Na₁₂[(ZnW₉O₃₄)₂WZn₃(H₂O)₂].46H₂O (**Zn₅W₁₉**),⁵⁸ H₃[PMo₁₂O₄₀].14H₂O (**PMo₁₂**),⁵⁹ H₄[PMo₁₁VO₄₀].14H₂O (**PMo₁₁V**),⁶⁰ and Na₇K₇[{(PW₉O₃₄)Ni₃(OH)(H₂O)₂(Ale)}₂Ni].34H₂O (**Ni₇W₁₈**, Ale = alendronate = [O₃PC(O)(C₃H₆NH₃)PO₃]⁴⁻)⁶¹ (Fig. S1, ESI[†]) has been synthesized following reported procedures. Besides, a polyethyleneimine polymer modified with guanidinium and octyl groups (PEI_{guan-oct}) was prepared by successive additions of praxadine and iodoctane to a DMF solution of 25 kDa multi-branched polyethyleneimine as previously described.^{62,63} The modified polymer was then purified by extensive dialysis to obtain an aqueous solution of PEI_{guan-oct} that was directly used for catalysis. The proportion of guanidinium and octyl groups grafted to the polymer were determined by ¹H NMR after lyophilization of the aqueous solution.⁶⁴ Alternatively, the commercial multibranch 25 kDa PEI was also used for comparison with the modified one. Catalytic experiments were performed in tinted glass vials in order to avoid any photochemical side reaction with the photosensitive flavin cofactor. In a typical experiment, PEI_{guan-oct} (2.5 mM), FMN (0.1 mM), POM (0.1 mM), the substrate (10 mM) and NADH (1 mM) were dissolved in deionized water (final volume 1 mL) and left under stirring, under 1 atmosphere of dioxygen, for 16 hours. The resulting solution was then transferred into 8 mL of acetonitrile, dried over magnesium sulfate, filtrated on silica gel and analyzed by gas chromatography (GC) in the presence of an internal standard (Table S1, ESI[†]). It is worth to note that the product of the reaction may also be isolated by ethyl acetate extraction of the aqueous solution. However, this technique was not chosen for GC quantification because it was demonstrated to be less quantitatively reliable than the above described drowning technique.

Results and discussion

Reactivity with POM **Zn₅W₁₉**

Since **Zn₅W₁₉** was previously used in the literature in combination with modified PEI and hydrogen peroxide to catalyze the oxidation of various small organic molecules,³³ we first focused our attention on studying its reactivity in the presence of the FMN-PEI_{guan-oct}-NADH. Control reactions involving different components were first performed using thioanisole as a substrate and the results are gathered in Table 1. All control experiments performed with a single reactant or binary combinations of reactants, e.g. NADH, FMN, PEI_{guan-oct} and/or **Zn₅W₁₉**, showed no product formation, in contrast to those performed with tertiary combinations of FMN and NADH, with either PEI or **Zn₅W₁₉**. The combination of PEI, FMN and NADH gave a 11% yield in sulfoxide with respect to NADH after 16 hours of reaction. This was not unexpected since the FMN, buried into the microenvironment of the PEI, had already been shown to be able to activate dioxygen to perform the Baeyer-Villiger oxidation.⁶⁴ The combination of **Zn₅W₁₉**, FMN and NADH gave a 40% yield in sulfoxide after 16 hours of reaction. The same result was also found for the FMN/PEI_{guan-oct}/**Zn₅W₁₉**/NADH full system. This was more surprising since it was previously demonstrated that in absence of

the modified polymer, NADH could not efficiently reduce the FMN.⁴⁹ This point will be discussed below in a paragraph dedicated to mechanistic studies. Finally, it is also worth to note that control reactions performed with the full system but in the absence of dioxygen only gave traces of sulfoxide, clearly demonstrating the aerobic character of the sulfoxidation process. These product traces may be explained by the difficulty to fully degas aqueous solutions, even by using freeze-pump techniques.

Table 1. Aerobic oxidation of thioanisole in the presence of the various components of the catalytic system in deionized water.

Reactants	Yield (%)	
	Sulfoxide	Sulfone
NADH	0 (± 0) ^(a)	0 (± 0) ^(a)
NADH + Zn₅W₁₉	0 (± 0) ^(a)	0 (± 0) ^(a)
NADH + FMN	0 (± 0) ^(a)	0 (± 0) ^(a)
NADH + PEI _{guan-oct} + Zn₅W₁₉	0 (± 0) ^(a)	0 (± 0) ^(a)
	5 (± 3) ^(b)	0 (± 0) ^(b)
NADH + PEI _{guan-oct} + FMN	11 (± 6) ^(a)	0 (± 0) ^(a)
NADH + FMN + Zn₅W₁₉	40 (± 2) ^(a)	0 (± 0) ^(a)
	82 (± 3) ^(b)	14 (± 7) ^(b)
NADH + PEI _{guan-oct} + FMN + Zn₅W₁₉	40 (± 5) ^(a)	0 (± 0) ^(a)
	75 (± 2) ^(b)	9 (± 6) ^(b)

Yields of sulfoxide and sulfone calculated with respect to the amount of NADH introduced in the solution and analyzed by GC. Conditions: [NADH] = 1 mM; [**Zn₅W₁₉**] = 0.1 mM; [FMN] = 0.1 mM; [PEI_{guan-oct}] = 2.5 mM; [thioanisole] = 10 mM at room temperature, P_{O₂} = 1 atm., for (a) 16 h and (b) 72 h. Control experiments with the full system but in the absence of O₂ only gave traces of sulfoxide.

Fig. 1 shows the yield for oxidation of thioanisole in water, under 1 atmosphere of O₂ at room temperature, as a function of time for 72 hours of reaction. When **Zn₅W₁₉** was combined to FMN-PEI_{guan-oct} and NADH, the sulfoxide and the sulfone were respectively formed in 75% and 9% yields with respect to the amount of NADH added to the solution. Under the same conditions, but in the absence of polymer, the kinetics was very similar and the final yields, 82% in sulfoxide and 14% in sulfone respectively, were even slightly better. However, the control reaction in the absence of FMN, gave less than 5% yield in sulfoxide after 72 hours of reaction. In order to better understand why catalysis was efficient even in the absence of polymer, we measured the reduction of 0.1 mM FMN by 1 mM NADH under the above-mentioned conditions and one could observe that the FMN was reduced with a similar rate both in the presence and in the absence of 2.5 mM polymer (Fig. S2, ESI[†]). This is clearly different from previous data obtained at lower concentrations of FMN (0.05 mM) and NADH (0.5 mM) for which the FMN needed to be incorporated into the PEI_{guan-oct} (1.25 mM) in

order to be reduced.⁴⁹ This concentration depending behavior could explain why the presence of FMN, NADH and **Zn₅W₁₉** is enough to perform catalysis in good yield since the reduced FMN can activate dioxygen and produce H₂O₂ that is then used as an oxidant by **Zn₅W₁₉** to perform the reaction. The formation of hydrogen peroxide was indeed demonstrated under both conditions using Quantofix[®] peroxide test sticks. Interestingly, this H₂O₂ concentration was shown to be stable in the absence of substrate, meaning that **Zn₅W₁₉** did not react with H₂O₂ or simply formed a stable **Zn₅W₁₉**-OOH hydroperoxo species if no substrate was available (see below).

Fig. 1. Time course for the catalytic oxidation of thioanisole into sulfoxide and sulfone in the presence of 0.1 mM POM **Zn₅W₁₉**, 0.1 mM FMN, 10 mM thioanisole and 1 mM NADH with (red triangles) and without (blue circles) 2.5 mM PEI_{guan-oct}, and without FMN (green squares), in water, at room temperature and under P_{O₂} = 1 atm.

Conversely, as soon as thioanisole was introduced in the solution, the H₂O₂ produced from O₂ was consumed in the presence of **Zn₅W₁₉** (Fig. 2). The stability of **Zn₅W₁₉** under the considered experimental conditions was studied. The POM was isolated from the catalytic medium by addition of cesium chloride before and after the catalytic event (see ESI[†] for details). First, a comparison of the IR spectrum of pristine **Zn₅W₁₉** with that of the powder isolated from the reacting medium before the catalytic event evidenced that the POM was stable in aqueous solution in the presence of NADH, FMN and PEI_{guan-oct} (Fig. S3, ESI[†]). Second, it appeared that the POM isolated from the same reacting medium but after addition of thioanisole and stirring at room temperature for 16 h presented exactly the same IR features than those of the POM isolated before catalysis (Fig. S3, ESI[†]). This strongly suggested that **Zn₅W₁₉** was stable throughout the catalytic process, which was confirmed by EDX measurements on the recovered catalyst (W : Zn ratio : theoretical 19 : 5, experimental 19 : 6.1). This is also supported by recyclability experiments, which show a steady increase in sulfoxide and sulfone after three successive injections of NADH at 0, 24 and 48h of reaction (Fig. S4, ESI[†]). It is also noteworthy that under such conditions, the formation of Ishii-Venturello complexes can be excluded, as such species only form in the presence of large amounts of H₂O₂⁶⁵ whereas, on the contrary, under our conditions, H₂O₂ is produced *in situ* in low concentration and is readily consumed for the oxidation of the substrate.

The mechanism presented in Scheme 2 can then be proposed. NADH first reduces the FMN whether it is incorporated into the polymer or not. However, the reduced FMNH₂ does not reduce **Zn₅W₁₉** as it could have been originally envisioned, but instead reacts with O₂ to produce H₂O₂ in solution. The fact that **Zn₅W₁₉** only consumes H₂O₂ in the presence of thioanisole suggests that **Zn₅W₁₉** forms a hydroperoxo intermediate under such conditions. This intermediate then oxidizes thioanisole into methyl phenyl sulfoxide.

The scope of the reaction was then extended to substrates bearing various substituents on the para position of thioanisole (Table 2). Electron donating groups such as methyl did not affect the yield of the reaction with ca. 55% yield after 30 hours for both thioanisole and 4-methyl-thioanisole. Mesomeric donating groups such as methoxy improved the yield up to 65% while attracting mesomeric groups such as nitro gave no product at all. This clearly identified the nucleophilic activity of thioanisole for its reaction with the proposed **Zn₅W₁₉**-OOH intermediate. Finally, the surprising good reactivity of the *para*-bromo substituted thioanisole could be explained by the fact that, in this case, the mesomeric donating activity clearly overcomes the electron withdrawing activity of the bromide substituent.

Fig. 2. H₂O₂ concentrations measured after 6 hours of reaction under aerobic conditions in the presence of 0 to 10 mM thioanisole and of 2.5 mM PEI_{guan-oct}, 0.1 mM FMN and 1 mM NADH with (blue squares) and without 0.1 mM **Zn₅W₁₉** (red triangles).

Table 2. Aerobic oxidation of various thioethers catalyzed by **Zn₅W₁₉** and FMN-PEI_{guan-oct} by using NADH and O₂ in water.

Substrates	Yield (%) ^a

Conditions: [NADH] = 1 mM; [**Zn₅W₁₉**] = 0.1 mM; [FMN] = 0.1 mM; [PEI_{guan-oct}] = 2.5 mM; [substrate] = 10 mM at room temperature, under P_{O₂} = 1 atm., reaction time: 30h.

Scheme 2. Proposed reaction scheme for the oxidation of thioanisole by **Zn₅W₁₉** and FMN-PEI_{guan-oct} in the presence of NADH.

Comparison of reactivity with three other POMs

The catalytic oxidation of thioanisole was also studied with other POMs, the molybdenum POM **PMo₁₂**, the molybdenum/vanadium POM **PMo₁₁V** and the tungsten/nickel POM **Ni₇W₁₈** (Fig. S1, ESI[†]). For the sake of comparison, the activities of the various POMs were studied either in the presence of the modified polymer (PEI_{guan-oct}) or in the presence of the commercial one (PEI_{com}). The obtained data are listed in Table 3.

Table 3. Aerobic oxidation of thioanisole by various POMs in the presence of NADH and O₂ and using FMN alone or incorporated into PEI_{guan-oct} or PEI_{com}.

POMs	Yield (%) ^a	Yield (%) ^a	Yield (%) ^a
	with PEI _{guan-oct}	with PEI _{com}	without PEI
Zn₅W₁₉	50 (±4)	63 (±2)	55 (±5)
PMo₁₂	51 (±7)	0 (±0)	1.5 (±1)
PMo₁₁V	40 (±7)	0 (±0)	5 (±1)
Ni₇W₁₈	45 (±5)	23 (±4)	8 (±1)

(a) Yields of sulfoxide and sulfone formed with respect to the amount of NADH introduced in aqueous solution and analyzed by GC. Conditions: [NADH] = 1 mM; [POM] = 0.1 mM; [FMN] = 0.1 mM; [PEI_{guan-oct}] or [PEI_{com}] = 2.5 mM; [thioanisole] = 10 mM, at room temperature, under P_{O₂} = 1 atm., reaction time 24 h.

For all POMs, when the FMN was incorporated into the modified polymer, solely the corresponding sulfoxide was observed after 24 hours of reaction, with yields measured between 40 and 51%. Interestingly, when the FMN was associated to the commercial PEI, the differences in yields were much larger, ranging from 0% for **PMo₁₂** and **PMo₁₁V** to 63 % for **Zn₅W₁₉**. With **Zn₅W₁₉**, the yield in sulfoxide is thus rather high after 24 h of reaction in the absence of polymer, which confirms that the association of this POM with the polymer does not influence its reactivity for sulfoxidation at these

concentrations. On the contrary, **PMo₁₂** and **PMo₁₁V** only present significant catalytic activities when they are associated to PEI_{guan-oct}. Such effect of the local microenvironment provided by the polymer was previously observed for other metal catalyzed reactions such as phosphate transesterification reactions.⁶³ As expected, the IR spectra of these species isolated from the aqueous medium (pH = 5.3) before the catalytic event revealed the presence of a mixture of phosphomolybdate species, as evidenced by the splitting of the P-O band found at 1057 cm⁻¹ for **PMo₁₂** and **PMo₁₁V** (Fig. S5, ESI[†]). However, the IR spectra of the POMs isolated before and after the catalytic processes are strictly similar, evidencing no evolution of the system during the oxidation of the substrate (Fig. S5, ESI[†]). Besides, since it was previously shown that, even in the absence of POM, H₂O₂ was produced by the system, the difference of reactivity between the phosphomolybdate and the phosphotungstate species should be related to an event prior to the formation of H₂O₂. There are, *a priori*, two hypotheses to explain the catalytic oxidation of thioanisole by the considered POM catalysts: (i) the reduced FMN reacts with O₂ to generate H₂O₂ which then reacts with the POM catalyst, as it was observed for **Zn₅W₁₉**, or, (ii) the reduced FMN is directly reducing the POM which then performs the reductive activation of dioxygen as originally envisioned in Scheme 1. Importantly, as soon as NADH was added to a solution of FMN-PEI containing **PMo₁₂** and **PMo₁₁V**, the pale-yellow solutions turned green, suggesting the reduction of Mo(VI) centres. This reduction was confirmed by UV-Visible spectroscopy, with the appearance of a band characteristic of reduced POM heteropolyblues (Fig. 3a and S6, ESI[†]).⁶⁶ One may note that the position of the band (710 nm) coincides with that observed for the α -IV-PMo₁₂ four-electron reduced species.⁶⁷ Conversely, the simple use of NADH in solution, without FMN, did not allow the reduction of molybdenum centres (Fig. 3b).

Fig. 3. UV-Visible spectra of aqueous solutions of (a) **PMo₁₂** (0.1 mM) and FMN (0.1 mM) followed for 16 min. after addition of NADH (1 mM) and (b)

PMo₁₂ (0.1 mM) followed for 16 min. after addition of NADH (1 mM). All experiments have been performed under anaerobic conditions.

It is worth to note that the reduction of Mo(VI) in the case of **PMo₁₁V** implies that V(V) was also reduced since its reduction potential is lower than the one of Mo(VI). Besides, by following the variations with time of the absorbance at 710 nm in the presence of FMN-PEI_{guan-oct} and FMN-PEI, respectively, it can be observed that the reduction of **PMo₁₂** is more efficient using the artificial reductase based on the modified polymer, FMN-PEI_{guan-oct} (Fig. S7, ESI[†]). Clearly, under such conditions, the reduced POM better activates O₂, which reinforces the hypothesis that the catalytic event could indeed first involve the reduction of the POM, followed by the reductive activation of dioxygen. All these observations lead to the proposed mechanism presented in Scheme 3. We can note that the difference in mechanism observed for **Zn₅W₁₉** and **PMo₁₂** agrees with the fact that polyoxomolybdates are by far more easily reduced than polyoxotungstates.⁶⁸

As mentioned above, the catalytic activity of **Zn₅W₁₉** is similar using PEI_{guan-oct} and PEI_{com} while **PMo₁₂** and **PMo₁₁V** only oxidize thioanisole in presence of PEI_{guan-oct}. We have investigated a second polyoxotungstate, the **Ni₇W₁₈** nickel complex Na₇K₇[{[(PW₉O₃₄)Ni₃(OH)(H₂O)₂(Ale)₂Ni]}₂·34H₂O]. It has been evidenced that **Ni₇W₁₈** exhibited an intermediate catalytic behavior, showing the richness of the present system. Indeed, while the yield in oxidized products is higher with PEI_{guan-oct}, this POM is also significantly active with PEI_{com} (see Table 3). Finally, as for **Zn₅W₁₉**, IR characterization of the POM before and after the catalytic event (Fig. S8, ESI[†]) strongly suggests that this POM is stable under the considered catalytic conditions.

Scheme 3. Proposed reaction scheme for the oxidation of thioanisole by **PMo₁₂** and FMN-PEI_{guan-oct} in the presence of NADH.

Conclusions

The activity of polyoxomolybdates and polyoxotungstates in combination with an artificial reductase and NADH has been studied for the aerobic oxidation of thioanisole derivatives. All POMs have demonstrated a catalytic activity in the presence of the artificial reductase under atmospheric pressure, in water and at room temperature. To the best of our knowledge, this represents the first evidence of a sulfoxidation activity for POMs under such mild conditions. Importantly, the obtained

yields are comparable or even higher for cheap one-step and large-scale synthesized POMs such as $\text{Na}_{12}[(\text{ZnW}_9\text{O}_{34})_2\text{WZn}_3(\text{H}_2\text{O})_2]\cdot 46\text{H}_2\text{O}$ or $\text{H}_3[\text{PMo}_{12}\text{O}_{40}]\cdot 14\text{H}_2\text{O}$ than those previously reported for the manganese(III)-meso-tetra(pentafluorophenyl)porphyrin, known as one of the best metalloporphyrin-based catalyst for oxidation reactions.⁴⁹ Two different mechanisms have been brought out. In the case of $\text{Na}_{12}[(\text{ZnW}_9\text{O}_{34})_2\text{WZn}_3(\text{H}_2\text{O})_2]\cdot 46\text{H}_2\text{O}$, the artificial reductase does not transfer electrons to the POM but instead reduces *in situ* O_2 into H_2O_2 which then reacts with the inorganic anion to perform sulphide oxidation. We can note that the recyclability of the system was evidenced. Conversely, $\text{H}_3[\text{PMo}_{12}\text{O}_{40}]\cdot 14\text{H}_2\text{O}$ is reduced by the artificial reductase and can then catalyze itself the reductive activation of O_2 to perform the sulfoxidation reaction. Also, the investigated $[\text{PMo}_{11}\text{VO}_{40}]^{4-}$ species appeared to react similarly to $[\text{PMo}_{12}\text{O}_{40}]^{3-}$. Now, considering the tremendous wide range of applications of POMs in oxidation catalysis, we are considering extending this study to other reactions, in particular the oxidation of alkenes and alkanes.
