Abstract

1-Propyl-2,3-dimethyl-1H-imidazol-3-ium ([pmIm]⁺), 3-(2,3-dihydroxypropyl)-1,2-dimethyl-1H-imidazol-3-ium ([dhmIm]⁺) and 1-benzyl-2,3-dimethyl-1H-imidazol-3-ium ([bzmIm]⁺) cations were used as organic templates for crystallizing SAPO-5 with AFI microporous framework. The physico-chemical influences of the functional groups of the templates (e.g. polarity/hydrophilicity, molecular dimension and size) on SAPO-5 formation were investigated. The results revealed that the crystallization rate, crystallinity and solid yield could be enhanced by increasing the polarity/hydrophilicity of the templates. In addition, the isomorphous Si substitution, morphology and particle size of the resulted SAPO-5 were also affected by the substituted groups of the imidazolium

templates. The thermogravimetry results further supported that the selection of organic template with proper polarity/hydrophilicity could be crucial to obtain SAPO-5 with high porosity (S_{BET} , S_{mic} , S_{ext} and V_{total}) as high polar/hydrophilic template exhibited stronger chemical interaction with the AFI framework during template removal process *via* calcination process.

Keywords: SAPO-5; Microporous material; Hydrothermal synthesis; Imidazolium template; Functional group; Polarity.

1. Introduction

The aluminophosphate (AlPO-*n*) and silicoaluminophosphate (SAPO-*n*) crystalline solids are zeolite-like materials with microporous framework that have been widely used in catalysis, adsorption and separation [1–3]. Recently, they have found new applications in nanotechnology, biotechnology and medical diagnosing [4–6]. A rational synthesis of these microporous materials with unique structures and properties is hence highly desired, but remains challenging.

Recently, several works have been devoted to understand the crystallization behavior of the AlPO-*n* and SAPO-*n* materials [7, 8]. Nevertheless, the crystal growth on a microscopic level are still not well-understood because the formation of these crystalline solids is depending on many synthesis parameters which include the molar ratio of reagents, solvent content, hydrothermal temperature, crystallization and aging times, the selection of templates, and so on [7–9]. Certainly, organic templates play a crucial role during the crystallization process by residing within the lattice of inorganic framework *via* non-chemical interaction, hence stabilizing the crystal structure and governing the morphology and porosity of the solid product [10]. In the synthesis of nanoporous materials, organic templates often serve as space fillers, structure directing agents, and/or true templating agents to facilitate the development of a specific porous framework [11, 12]. To date, a few groups of nitrogen-

based organic substances like amines [13, 14], quaternary ammonium [15, 16], imidazolium [17, 18] and pyridinium [19] ions have been used as organic templates to prepare AlPO-*n* and SAPO-*n* materials.

SAPO-5 (with AFI framework) is a large-pore silicoaluminophosphate material. Its one-dimensional cylindrical framework structure is made up of 12-membered ring channels (7.3 Å) and constructed by SiO₄, AlO₄ and PO₄ tetrahedrals forming a negative framework [20]. It is found that the morphology and size of SAPO-5 crystals are strongly depending on the synthesis conditions (synthesis recipe, temperature, time duration and heating technique) and properties of the organic templates (ionic charge, hydrophobicity/hydrophilicity, molecular shape and size). AFI framework structure can be templated using various types of organic templates such as triethylamine [21], tetraethylammonium hydroxide [22], tripropylamine (TPA) [23], tetramethylpyrazine and N',N',N',N'-tetramethyl-1,3-propanediamine (TMPD) [24] and 1-ethyl-2,3-dimethyl imidazolium hydroxide [25]. By using different organic templates, SAPO-5 solids with rod, plate, barrel, prism, broom-like, flower-like, disc-like, spheroidal shapes have been reported [26–30]. Imidazolium ionic liquids have been explored as recyclable and reusable synthesis mediums. Therefore, the influence of imidazolium-based templates bearing different functional groups on the formation of SAPO-5 is worth to be further explored.

In this study, microporous SAPO-5 materials have been synthesized under hydrothermal condition using imidazolium-based templates. Three imidazolium cations containing different functional groups and polarity/hydrophilicity, namely 1-propyl-2,3-dimethyl-1H-imidazol-3-ium ([pmIm]⁺), 3-(2,3-dihydroxypropyl)-1,2-dimethyl-1H-imidazol-3-ium ([dhmIm]⁺) and 1-benzyl-2,3-dimethyl-1H-imidazol-3-ium ([bzmIm]⁺), have been synthesized in the laboratory before being characterized and used in the hydrothermal synthesis of SAPO-5. Then, the effects of these organic templates on the crystallization rate, degree of crystallinity, solid yield, morphology, crystallite size, elemental composition and porosity of the solid products are investigated by using various characterization techniques.

2. Experimental

2.1. Preparation of imidazolium templates

2.1.1. Preparation of imidazolium ionic salts

1-Propyl-2,3-dimethyl-1H-imidazol-3-ium bromide ([pmIm]Br), 3-(2,3-dihydroxypropyl)-1,2-dimethyl-1H-imidazol-3-ium 4-methylbenzenesulfonate ([dhmIm]OTs) and 1-benzyl-2,3-dimethyl-1H-imidazol-3-ium chloride ([bzmIm]Cl) were synthesized according to the procedures given in the Supplementary Information with slight modifications [7, 25, 31].

2.1.2. Preparation of [pmIm]OH, [dhmIm]OH and [bzmIm]OH imidazolium hydroxide solutions

1-Propyl-2,3-dimethyl-1H-imidazol-3-ium hydroxide ([pmIm]OH), 3-(2,3-dihydroxypropyl)-1,2-dimethyl-1H-imidazol-3-ium hydroxide ([dhmIm]OH) and 1-benzyl-2,3-dimethyl-1H-imidazol-3-ium hydroxide ([bzmIm]OH) template solutions were prepared by ion exchanging the respective ionic salts with Amberlite® IRN-78 hydroxide ion-exchange resin (Sigma-Aldrich). The resulting solutions were separated from the resins by filtration and titrated with 0.1 M HCl solution to ensure 90% OH⁻ ion exchange was achieved. The template solution in hydroxide form was then concentrated to 33.0 wt.% at 50 °C and stored at room temperature for further use.

2.2. Crystallization of SAPO-5

Typically, the SAPO-5 was synthesized as follows: Aluminum triisopropoxide (4.334 g, ≥99.99%, Sigma-Aldrich), organic template solution (30.108 g for [pmIm]OH, 39.696 g for

[bzmIm]OH or 39.221 g for [dhmIm]OH) and deionized water (6.464 g) were added and stirred in a polypropylene bottle for 35 min. Then, H₃PO₄ (7.333 g, 85%, Acros Organics) was added into the mixture in a dropwise manner for 15 min to produce a precursor mixture with a chemical composition of 1Al₂O₃:3P₂O₅: 6SDAOH:180H₂O where SDAOH was the imidazolium hydroxide template used. The precursor mixture was transferred into an autoclave (100 mL) and heated at 180 °C for crystallization. After cooling, the solid product was washed with distilled water until pH 7 and oven dried at 80 °C. The final powder samples synthesized with [pmIm]OH, [bzmIm]OH and [dhmIm]OH were labelled as pmIm-*n*, bzmIm-*n* and dhmIm-*n*, respectively, where *n* indicated the synthesis time in hour.

2.3. Characterizations

The XRD patterns of the samples were recorded with a Bruker-AXS D8 diffractometer (Cu K α radiation, $\lambda = 1.5418 \text{ \AA}$, 40 kV, scan speed of 0.2°/min, step size of 0.02°). The crystallinity was estimated by comparing the intensity of the three most intense bands at 7.51°, 19.92° and 22.52° of dhmIm-2.5 (as a reference of 100% crystallinity). The solid yield was determined in relation to the mass of the starting materials by using the following equation:

$$\text{Solid yield (\%)} = \frac{\text{Mass of SAPO-5 solid obtained (g)}}{\text{Initial mass of 1 mol of P}_2\text{O}_5 \text{ and Al}_2\text{O}_3 \text{ (g)}} \times 100\%$$

The morphological properties of samples were characterized with a Leo Supra 50VP scanning electron microscope (FESEM) operated at 20 kV and 10 μ A. The IR spectra were recorded with an infrared spectrometer (Perkin Elmer's System 2000) using the KBr pellet method. The bulk elemental composition of the solids was analyzed using an XRF spectrometer (Phillips X'Unique). The inorganic and organic components in the non-calcined solids were studied by a thermogravimetry analyzer

(Perkin Elmer's TGA 4000, 20 °C/min air flow). Nitrogen adsorption-desorption isotherms were obtained at −196 °C using a Micromeritics ASAP 2010 apparatus after outgassing the samples at 250 °C under vacuum overnight.

3. Results and discussion

3.1. XRD analysis

In this study, SAPO-5 samples have been synthesized using three different imidazolium cations, namely, [pmIm]⁺, [bzmIm]⁺ and [dhmIm]⁺ (Table 1). These cations possess similar backbone molecular structures but with different functional groups. Consequently, the templates have different molecular sizes, geometries and electronegativities, resulting in different polarities of the imidazolium molecules. In respect to this, Sanderson's model of intermediate electronegativity (S_{int}) is used to describe the polarities of the imidazolium molecules [32]. As anticipated, [dhmIm]⁺, which containing polar diol group, has the highest S_{int} (2.747), followed by [bzmIm]⁺ (S_{int} = 2.693) that has better electron donation ability than [pmIm]⁺ (S_{int} = 2.605).

The XRD analysis was used to monitor the crystallization evolution of SAPO-5 samples. It was shown that the most polar [dhmIm]⁺ template enhanced the crystallization rate of SAPO-5. Significant XRD peaks at $2\theta = 7.51^\circ$, 15.01° , 19.92° , 21.12° , 22.52° and 26.13° were detected in dhmIm-0.3 indicating that crystalline AFI framework had started to form in this solid within the first 0.3 h of heating (Fig. 1c). In contrast, the pmIm and bzmIm solids remained as amorphous at this early stage as no XRD peaks were observed (Fig. 1a, b). The crystallinity of the [dhmIm]⁺-templated sample increased linearly with time and reached its maximum (100% crystallinity) within 2.5 h (Fig. 1d). Further heating the sample, however, promoted co-crystallization of tridymite dense phase (XRD results not presented here).

On the other hand, the crystallization profiles of both pmIm-*n* and bzmIm-*n* samples followed a sigmoid function (Fig. 1d). The bzmIm-*n* samples had the longest induction time before nucleation and substantial crystallization only occurred after 8 h of heating (Fig. 1b, d). The bzmIm-10 achieved 87% of crystallinity after 10 h of heating, and no competing phase was co-crystallized in this sample. For the pmIm-*n* series, significant crystallization of SAPO-5 started around 1.3 h of heating (Fig. 1a), but the samples had the slowest crystallization kinetics as compared with the samples templated by [dhmIm]⁺ and [bzmIm]⁺ (Fig. 1d). After 5 h of heating, only 68% of crystallinity was recorded for the bzmIm-5 sample. Of note, six additional XRD signals (marked as *) were observed at high 2θ range which could be attributed to a periodic crystal-like arrangement of the [pmIm]⁺ molecules within the solid sample (Fig. 1a) [33]. These six XRD peaks, however, disappeared after the template was removed by calcination.

The XRD results suggested that the [dhmIm]⁺ might have promoted the crystallization rate *via* its diol group where this functional group could enhance the positive charge of the imidazolium ring by withdrawing its electron density. As a result, the imidazolium ring became more polarized and strong templating effect was therefore enhanced [34]. On the other hand, the π electrons from the benzyl group of [bzmIm]⁺ were likely to be attracted to the imidazolium ring and thus the imidazolium cation became less polarized. Consequently, the templating power of [bzmIm]⁺ was reduced and causing the bzmIm-*n* samples experienced the longest induction period before significant crystalline phase was detected by XRD.

3.2. Solid yield analysis

Fig. 2 shows the yield of solid products obtained using different templates versus heating time. Before hydrothermal crystallization, the initial precursor mixtures of the three synthesis series (pmIm-

0, bzmIm-0 and dhmIm-0) gave about 4.0–5.3% solid yields. During the crystallization process, however, the solid yields varied depending on the type of imidazolium templates used. For example, the sample prepared from the most polar [dhmIm]⁺ template ($S_{\text{int}} = 2.747$) exhibited fast increment in the product yield where 89.6% of solid product was obtained after 2.5 h of hydrothermal crystallization. In contrast, lower solid product yield was gained when less polar [pmIm]⁺ (39.6%) and [bzmIm]⁺ (6.2%) were used after 2.5 h of hydrothermal crystallization. For pmIm-5 and bzmIm-10, only 68.4% and 42.7% of solid products were successfully recovered, respectively. Hence, it can be seen that the degree of crystallinity and the solid yield have strong correlation with the polarity of the imidazolium template.

3.3. FESEM analysis

The FESEM micrographs of SAPO-5 prepared using [pmIm]⁺, [bzmIm]⁺ and [dhmIm]⁺ templates are shown in Fig. 3. The pmIm-10 crystallites are of a plate-like morphology with a dimension of about 350 nm wide and 130 nm thick (Fig. 3a, b). The FESEM data hence agrees well with the XRD results where this sample exhibits broader XRD peaks (Fig. 1a) owing to their submicron crystallite size [35]. Meanwhile, hexagonal prism and cubic-like SAPO-5 crystallites (bzmIm-10) with an average size of 560 nm are produced when [bzmIm]⁺ template is employed (Fig. 3c, d). On the other hand, the SAPO-5 crystallites (dhmIm-2.5), synthesized with the polar [dhmIm]⁺, exhibit typical hexagonal prism morphology with sizes up to a few micrometers (Fig. 3e, f). As can be seen, the crystallites have very high tendency to agglomerate forming larger secondary particles with sizes greater than 10 μm . Hence, the results clearly show that the morphologies of the three SAPO-5 samples are significantly affected by the polarity, functional group and geometry of the imidazolium templates used.

3.4. Elemental analysis

The effect of various imidazolium templates used on the final chemical composition (P:Al:Si ratio) of the SAPO-5 samples (pmIm-5, bzmIm-10 and dhmIm-2.5) was also studied (Table 2). The data show that dhmIm-2.5 experiences the highest degree of isomorphous incorporation of Si into the AFI aluminophosphate framework ($\text{Si}/(\text{P}+\text{Al}+\text{Si}) = 0.068$) while pmIm-5 has the least Si incorporated among the three samples ($\text{Si}/(\text{P}+\text{Al}+\text{Si}) = 0.054$). Thus, the results of the elemental analysis reveal that the polar [dhmIm]⁺ template tend to attract silicate anionic species strongly, and hence indirectly promoting the participation and isomorphous substitution of Si into the formation of microporous AFI framework.

3.5. TG/DTG measurements

The chemical and supramolecular interactions of the imidazolium templates with the microporous solids were studied *via* thermogravimetry analysis. The thermogravimetry data of the as-synthesized SAPO-5 are summarized in Table 3. In addition, the TGA/DTG profiles of free [pmIm]OH, [bzmIm]OH and [dhmIm]OH templates are also shown in Fig. 4 whereas the TGA/DTG profiles of the as-synthesized pmIm-5, bzmIm-10 and dhmIm-2.5 samples are shown in Fig. 5. As can be seen, those free imidazolium hydroxide templates exhibit two steps of weight loss (Fig. 4). The first endotherm below 220 °C is due to the adsorbed water ([pmIm]OH: 3.59%, [bzmIm]OH: 4.48%, [dhmIm]OH: 19.41%) while the second step of weight loss around 210–480 °C is attributed to the decomposition of the imidazolium hydroxides ([pmIm]OH: 96.40%, [bzmIm]OH: 95.52%, [dhmIm]OH: 60.88%). The thermogravimetry data show that [pmIm]OH and [bzmIm]OH have completely combusted at 385 °C and 383 °C, respectively. In contrast, the relatively polar [dhmIm]OH molecules, which contain diol

groups, require higher temperature (496 °C) for partial decomposition, leaving 19.79% of non-combusted carbon even after 800 °C.

When the imidazolium templates are confined within the solids, the as-synthesized SAPO-5 samples show different weight loss regions with multiple steps of thermal decomposition (Fig. 5). For example, a slight difference is shown in the first step of weight loss at 210 °C by the pmIm-5, bzmIm-10 and dhmIm-2.5 samples (4.76%, 3.85% and 1.21%, respectively). The amount of water adsorbed is inversely proportional to the hydrophilicity/polarity of imidazolium templates employed where dhmIm-2.5 which containing polar [dhmIm]⁺ template adsorbs the least amount of water. Besides, the amount of template occluded in the micropores of SAPO-5 is also different. The bzmIm-10 has the lowest amount of template trapped in the pores (9.47%, see Table 3) due to its large molecular size which allows its limited accommodation in the micropores, whereas dhmIm-2.5 has the largest amount of confined template (12.90%), followed by pmIm-5 (10.77%). As a result, dhmIm-2.5 adsorbs lesser water than pmIm-5 and bzmIm-10. Moreover, the cationic template molecules, which are confined in the porous framework, also experience delayed thermal decomposition. For example, full decomposition of [pmIm]⁺ within SAPO-5 is observed at 515 °C, and it is 128 °C higher than that of the free [pmIm]⁺ template (385 °C). For bzmIm-10 and dhmIm-2.5, similar trend is also observed where the confined [bzmIm]⁺ and [dhmIm]⁺ decompose completely at higher temperatures (590 °C and 710 °C, respectively) in respect to their free counterpart (383 °C and 496 °C, respectively). Among the three as-synthesized SAPO-5 samples, dhmIm-2.5 requires the highest temperature to remove fully the occluded organic template. This can be explained by (i) the strong intra-/intermolecular hydrogen bonding between the [dhmIm]⁺ and the SAPO-5 framework, (ii) the supramolecular/confinement effect of the rigid microporous solid, and (iii) the formation of covalent bond *via* condensation reaction between the –OH groups of [dhmIm]⁺ with the defect sites (Al–OH, P–OH, Si–OH) of SAPO-5 in the microporous channels [36, 37].

3.6. Surface and texture properties

The properties of imidazolium templates not only affect the crystallization process and the morphology but also govern the porous properties of the resulted SAPO-5 samples. The nitrogen gas adsorption and desorption isotherms of the calcined SAPO-5 samples are shown in Fig. 6. All the samples (pmIm-5, bzmIm-10 and dhmIm-2.5) display Type I isotherm, which is characteristic of microporous materials [38]. Typically, the isotherms rise sharply and reach a plateau at low relative pressure (P/P_o). At higher relative pressure ($P/P_o > 0.4$), further nitrogen uptake with hysteresis loops is observed for the pmIm-5 and bzmIm-10 samples (Fig. 6). This H3 type-like hysteresis loop can be related to slit-shaped mesoporosity that is usually formed between submicron-sized particles [38]. However, no hysteresis loop is shown by the dhmIm-2.5 isotherm at high relative pressure. Instead, it shows an abrupt slight increase in nitrogen uptake at $P/P_o > 0.90$, which can be explained by the presence of small volume of macroporosity generated from close packing of the micron-sized SAPO-5 crystallites.

The dhmIm-2.5 exhibits the lowest microporosity ($S_{mic} = 181 \text{ m}^2/\text{g}$, see Table 2) due to partial collapse of the AFI microporous framework as a result of severe calcination temperature (800°C) needed to remove completely the strongly occluded $[\text{dhmIm}]^+$. In contrast, both pmIm-5 and bzmIm-10 have almost similar microporosity ($S_{mic} \sim 260 \text{ m}^2/\text{g}$) as $[\text{pmIm}]^+$ and $[\text{bzmIm}]^+$ are much easier to be decomposed and removed from the microporous channels (calcined at 550 and 600°C , respectively) due to their weaker interactions and occlusion in the SAPO-5 crystalline framework. The data in Table 2 show that the pmIm-5 sample has the highest specific BET surface area and pore volume ($269 \text{ m}^2/\text{g}$, $0.39 \text{ cm}^3/\text{g}$), followed by bzmIm-10 ($261 \text{ m}^2/\text{g}$, $0.35 \text{ cm}^3/\text{g}$) and dhmIm-2.5 ($182 \text{ m}^2/\text{g}$, $0.30 \text{ cm}^3/\text{g}$). Thus, the results indicate that smaller and less polar organic templates are more preferable in

crystallizing SAPO-5 with larger surface area and pore volume as they are loosely confined and weakly interacted in the SAPO-*n* frameworks.

Conclusions

As a conclusion, the effects of imidazolium templates with various functional groups in the crystallization of microporous SAPO-5 have been investigated. The results show that the polarity and molecular geometry of imidazolium templates govern several physico-chemical properties of the resulted SAPO-5. By using polar template such as [dhmIm]⁺, the crystallization rate and solid yield of SAPO-5 can be significantly enhanced. While the chemical composition is slightly affected upon changing the templates, a noteworthy change in the morphology of SAPO-5 is achieved. Different degree of template occlusion by crystalline microporous AFI framework has been observed where [dhmIm]⁺ with polar diol functional group interacts very strongly with the inorganic host, while [pmIm]⁺ with simple linear propyl chain is loosely bound to the framework. As a result, [pmIm]⁺ can be easily removed from the sub-micron crystallites using lower temperature calcination, producing SAPO-5 solids with the highest surface area, pore volume and microporosity. Hence, this study demonstrates that the selection of organic templates with proper geometry and contain hydrophobic functional groups is utmost important to produce SAPO-*n* with high microporosity and surface area.

Figures captions

Fig. 1. XRD patterns of (a) pmIm-*n*, (b) bzmIm-*n* and (c) dhmIm-*n* solids after various heating times, and (d) a plot of crystallinity versus respective crystallization heating time of pmIm-*n*, bzmIm-*n* and dhmIm-*n* samples. * shows the XRD diffraction peaks due to the periodic crystal-like arrangement of [pmIm]⁺ molecules in the SAPO-5 micropores.

Fig. 2. Solid yield profiles of (a) pmIm-*n*, (b) bzmIm-*n* and (c) dhmIm-*n* samples.

Fig. 3. FESEM images of (a,b) pmIm-5, (c,d) bzmIm-10 and (e,f) dhmIm-2.5 SAPO-5 crystals under different magnifications.

Fig. 4. TGA-DTG profiles of (a) [pmIm]OH, (b) [bzmIm]OH and (c) [dhmIm]OH.

Fig. 5. TGA-DTG profiles of as-synthesized (a) pmIm-5, (b) bzmIm-10 and (c) dhmIm-2.5 SAPO-5.

Fig. 6. Nitrogen gas adsorption and desorption isotherms of calcined (a) pmIm-5, (b) bzmIm-10 and (c) dhmIm-2.5 SAPO-5.

TABLES

Table 1

Molecular structure	Abbreviation	Molecular size ($\text{\AA}^3$) ^a	$S_{E,int}$ ^b
<p>1-Propyl-2,3-dimethyl-1H-imidazol-3-ium</p>	$[\text{pmIm}]^+$	$8.79 \times 5.03 \times 1.78$	2.605
<p>1-Benzyl-2,3-dimethyl-1H-imidazol-3-ium</p>	$[\text{bzmIm}]^+$	$9.19 \times 5.83 \times 4.88$	2.693
<p>3-(2,3-dihydroxypropyl)-1,2-dimethyl-1H-imidazol-3-ium</p>	$[\text{dhmIm}]^+$	$9.11 \times 4.88 \times 2.07$	2.747

^aComputed using HyperChem Release 8.0.8 software; ^bDetermined using Sanderson's model of intermediate

electronegativity, $S_{E,int} = \left(\Pi S_{E,Z}^x \right)^{(\Sigma x)^{-1}}$ [32].

Table 2

Samples	P/Al ratio ^a	Si/Al ratio ^a	Si/(P+Al+Si) ratio ^a	S _{BET} ^b (m ² /g)	S _{ext} ^c (m ² /g)	S _{mic} ^d (m ² /g)	V _{tot} ^e (cm ³ /g)
pmIm-5	0.85	0.105	0.054	269	23	246	0.39
bzmIm-10	0.87	0.105	0.056	261	11	250	0.35
dhmIm-2.5	0.83	0.134	0.068	182	1	181	0.30

^aMeasured by ICP-OES; ^bSpecific BET surface area; ^cExternal surface area; ^dMicropore surface area; ^eTotal pore volume.

Table 3

As-synthesized SAPO-5 samples	Weight loss (%)		Weight of inorganic residue (%)
	<200 °C	200 °C to x °C	
pmIm-5	4.76	10.77 ($x = 520$)	84.47
bzmIm-10	3.85	9.47 ($x = 600$)	86.68
dhmIm-2.5	1.21	12.90 ($x = 700$)	85.89

Research Highlights

- SAPO-5 is synthesized using imidazolium-based templates.
- Template's functional group affects crystallization and morphological profiles.
- Proper hydrophobicity is essential to control host-guest chemical interactions.
- Polar template interacts strongly with SAPO-5, hence high temperature calcination is needed.
