ON THE WEAK MAXIMIZING PROPERTIES

LUIS C. GARCÍA-LIROLA AND COLIN PETITJEAN

ABSTRACT. Quite recently, a new property related to norm-attaining operators has been introduced: the weak maximizing property (WMP). In this note, we define a generalised version of it considering other topologies than the weak one (mainly the weak* topology). We provide new sufficient conditions, based on the moduli of asymptotic uniform smoothness and convexity, which imply that a pair (X, Y) enjoys a certain maximizing property. This approach not only allows us to (re)obtain as a direct consequence that the pair (ℓ_p, ℓ_q) has the WMP, but also provides many more natural examples of pairs having a given maximizing property.

1. INTRODUCTION

Let X, Y be two real Banach spaces and let $T: X \rightarrow Y$ be a bounded linear operator (we will write $T \in \mathcal{L}(X, Y)$). A maximizing sequence for T is a sequence $(x_n)_n \subset X$ with $\|x_n\| = 1$ for every $n \in \mathbb{N}$ and such that $\lim_{n \rightarrow \infty} \|Tx_n\|_Y = \|T\|$. Next, we say as usual that $T: X \rightarrow Y$ attains its norm whenever there exists a vector $x \in X$ of norm 1 such that $\|Tx\|_Y = \|T\|$. Now following [5], a pair of Banach spaces (X, Y) is said to have the weak maximizing property (WMP) if for any bounded linear operator $T: X \rightarrow Y$, the existence of a non-weakly null maximizing sequence for T implies that T attains its norm. For instance, it is proved in [28, Theorem 1] that the pair (ℓ_p, ℓ_q) has the WMP whenever $1 < p < \infty$ and $1 \leq q < \infty$. That result was extended in [5, Proposition 2.2] to the pair $(\ell_p(\Gamma_1), \ell_q(\Gamma_2))$ where Γ_1, Γ_2 are arbitrary indices.

Needless to say that the theory of norm attaining operators finds many applications in both pure and applied mathematics. A motivation for the study of the WMP is the following application which was noted in [5] (and extends a former result due to J. Kover in the Hilbert case [22]): if (X, Y) has the weak maximizing property, $T \in \mathcal{L}(X, Y)$ and $K: X \rightarrow Y$ is a compact operator such that $\|T\| < \|T + K\|$, then $T + K$ is norm attaining. As a consequence, the authors could deduce that a pair (X, Y) has the weak maximizing property for some $Y \neq \{0\}$ if and only if X is reflexive.

In this note, we provide a new (possibly simpler) approach based on a comparison between the modulus of asymptotic uniform convexity of X and the modulus of asymptotic uniform smoothness of Y , and conversely (see Section 2 for precise definitions). Moreover, we consider the following related and quite natural properties.

Definition 1.1. Let X and Y be Banach spaces. Let τ_X and τ_Y be any topology on X and Y respectively. We say that the pair:

- (X^*, Y) has the weak* maximizing property (W*MP) if for any bounded linear operator $T: X^* \rightarrow Y$, the existence of a non-weak* null maximizing sequence for T implies that T attains its norm.

Key words and phrases. Norm attainment, Banach Space, Weak Maximizing Property, Asymptotic Uniform Smoothness, Asymptotic Uniform Convexity.

- (X, Y) has the τ_X -to- τ_Y maximizing property (τ_X -to- τ_Y MP) if for any bounded linear operator $T: X \rightarrow Y$ which is τ_X -to- τ_Y continuous, the existence of a non τ_X -null maximizing sequence for T implies that T attains its norm.

In this note, τ_X and τ_Y will mainly be the usual weak or weak* topologies. For instance, the WMP corresponds to the weak-to-weakMP. Notice that if the pair (X^*, Y) has the WMP then it also has the W*MP, and consequently the weak*-to-weakMP. Also, if X is reflexive, then a pair (X, Y) has the WMP if and only if (X, Y) has the W*MP if and only if (X, Y) has the weak*-to-weakMP. However, we will prove that these three properties do not coincide in general.

Remark 1.2. The definition of the above properties can be stated in terms of nets instead of sequences. Indeed, given an operator $T: X \rightarrow Y$, the following properties are equivalent:

- There exists a non τ_X -null maximizing sequence for T .
- There exists a non τ_X -null maximizing net for T .
- There exists a net which is maximizing for T and does not admit 0 as a τ_X -cluster point.

Clearly, i) $\Rightarrow$ ii). To see that iii) $\Rightarrow$ i), let $(x_\alpha)_\alpha \subset S_X$ be a net such that 0 is not a τ_X -cluster point and $\lim_\alpha \|Tx_\alpha\| = \|T\|$. Pick inductively α_n such that $\|Tx_{\alpha_n}\| \geq 1 - \frac{1}{n}$ and $\alpha_n \geq \alpha_m$ if $n \geq m$. Then the sequence $(x_{\alpha_n})_n$ is a subnet of $(x_\alpha)_\alpha$, so it is not τ_X -null, and it is maximizing for T . Finally, assume that ii) holds and let's prove iii). Let $(x_\alpha)_\alpha$ be a non τ_X -null net maximizing for T . Then 0 is not the only τ_X -cluster point of $(x_\alpha)_\alpha$, otherwise, all the subnets of $(x_\alpha)_\alpha$ would converge to 0, a contradiction (see e.g. [4]). Thus, there is a subnet $(y_\beta)_\beta$ of $(x_\alpha)_\alpha$ convergent to $y \neq 0$, and $(y_\beta)_\beta$ is also maximizing for T .

Remark 1.3. Replacing the WMP by the weak*-to-weak*MP, one can follow the lines of [5, Proposition 2.4] to obtain the following result: Suppose that (X^*, Y^*) has the weak*-to-weak*MP. Let $T, K: X^* \rightarrow Y^*$ be weak*-to-weak* continuous linear operators such that K is compact. If $\|T\| < \|T + K\|$ then $T + K$ is norm attaining.

We now describe the main findings of this paper. Throughout the paper, X and Y will denote real Banach spaces while X^* denotes as usual the topological dual of X . After recalling the definition of the modulus $\bar{\delta}_{X^*}^*(t)$ of weak* asymptotic uniform convexity and of the modulus $\bar{\rho}_Y(t)$ of asymptotic uniform smoothness in Section 2, we prove our first theorem in Section 3.

Theorem 3.1. *Let X, Y be Banach spaces. Assume that for every $t > 0$, $\bar{\delta}_{X^*}^*(t) \geq \bar{\rho}_Y(t)$ and, for all $t \geq 1$, either $\bar{\delta}_{X^*}^*(t) > \bar{\rho}_Y(t)$ or $\bar{\rho}_Y(t) > t - 1$. Then,*

- the pair (X^*, Y) has the weak*-to-weakMP.*
- If moreover $Y \equiv Z^*$ is a dual space, then the pair (X^*, Z^*) has the weak*-to-weak*MP.*
- If $\bar{\delta}_{X^*}^*(t) = t$, then (X^*, Y) has the W*MP for any Banach space Y .*

In particular, if X is reflexive then the pair (X^, Y) has the WMP.*

Since for any infinite sets Γ_1 and Γ_2 and for $1 < p < q < \infty$, it is well known that $\bar{\delta}_{\ell_p(\Gamma_1)}^*(t) = (1 + t^p)^{1/p} - 1 > (1 + t^q)^{1/q} - 1 = \bar{\rho}_{\ell_q(\Gamma_2)}$, our last theorem provides a new proof of the fact that the pair $(\ell_p(\Gamma_1), \ell_q(\Gamma_2))$ has the WMP. Note that the case $p = q$ also follows from the last theorem. In both papers [5, 28], the proof for the case $1 \leq q < p < \infty$ follows from Pitt's theorem asserting that any bounded operator $T: \ell_p \rightarrow \ell_q$ is compact and thus attains its norm. In fact, Pitt's theorem can also be generalised using the modulus $\bar{\rho}_X(t)$ of asymptotic uniform smoothness

of X and the modulus $\bar{\delta}_Y(t)$ of asymptotic uniform convexity of Y . Namely, if there exists $t > 0$ such that $\bar{\rho}_X(t) < \bar{\delta}_Y(t)$, then every bounded linear operator from X to Y is compact (see [17, Proposition 2.3], where this is stated only for $0 < t < 1$, but the proof works for any $t > 0$). We take advantage of this fact to deduce the next result.

Theorem 3.8. *Let X, Y be Banach spaces and $|\cdot|$ be an equivalent norm on X^* . If there exists $t > 0$ such that $\bar{\rho}_{|\cdot|}(t) < \bar{\delta}_Y(t)$, then*

- (1) *the pair (X^*, Y) has the weak*-to-weakMP.*
- (2) *If moreover $Y \equiv Z^*$ is a dual spaces, then (X^*, Z^*) has the weak*-to-weak* MP.*

In particular, if X is reflexive then (X^, Y) has the WMP.*

In Section 4, we discuss the case of some classical Banach spaces and the connections between several weak maximizing properties. Notably, we show in Proposition 4.2 that if X is reflexive, Y has the Dunford–Pettis property and (X, Y) has the WMP then (Y^*, X^*) has the weak*-to-weak*MP. Next, we prove that Schur spaces such as ℓ_1 are the best range spaces for the WMP: the pair (X, Y) has the WMP for any reflexive space X and any Schur space Y (Proposition 4.7). It follows from Theorem 3.1 (3) (and $\bar{\delta}_{\ell_1}^*(t) = t$) that ℓ_1 is also a very good domain for the W*MP (see Corollary 4.8) while this is not the case of every Schur space. Indeed, in Example 4.9 (Example 4.10 respectively) we provide a dual Banach space $Z = X^*$ with the Schur property and such that the pair $(X^*, \mathbb{R})$ fails the W*MP (the pair (X^*, ℓ_1) fails the weak*-to-weak*MP respectively). We end the paper by dealing with the classical James sequence spaces, Orlicz spaces and we also add some comments about the pair $(L_p([0, 1]), L_q([0, 1]))$.

2. PRELIMINARIES: ASYMPTOTIC UNIFORM SMOOTHNESS AND CONVEXITY

Consider a real Banach space $(X, \|\cdot\|)$ and let S_X be its unit sphere. For $t > 0$, $x \in S_X$ we consider

$$\begin{aligned}\bar{\delta}_X(t, x) &= \sup_{\dim(X/Y) < \infty} \inf_{y \in S_Y} \|x + ty\| - 1; \\ \bar{\rho}_X(t, x) &= \inf_{\dim(X/Y) < \infty} \sup_{y \in S_Y} \|x + ty\| - 1.\end{aligned}$$

The *modulus of asymptotic uniform convexity* of X is given by

$$\bar{\delta}_X(t) = \inf_{x \in S_X} \bar{\delta}_X(t, x),$$

and *modulus of asymptotic uniform smoothness* of X is given by

$$\bar{\rho}_X(t) = \sup_{x \in S_X} \bar{\rho}_X(t, x).$$

The space $(X, \|\cdot\|)$ is said to be *asymptotically uniformly convex* (AUC for short) if $\bar{\delta}_X(t) > 0$ for each $t > 0$ and it is said to be *asymptotically uniformly smooth* (AUS for short) if $\lim_{t \rightarrow 0} t^{-1} \bar{\rho}_X(t) = 0$. If X is a dual space and we considered only weak* closed subspaces of X then the corresponding modulus is denoted by $\bar{\delta}_X^*(t)$. The space X is said to be *weak* asymptotically uniformly convex* (AUC*) if $\bar{\delta}_X^*(t) > 0$ for each $t > 0$. We refer the reader to [17] and the references therein for a detailed study of these properties.

Let $p, q \in [1, \infty)$. We say that X is *weak* p -asymptotic uniformly convex* (abbreviated by p -AUC*) if there exists $C > 0$ so that $\bar{\delta}_X^*(t) \geq Ct^p$ for all $t \in [0, 1]$. Similarly, we say that X is *q -asymptotic uniformly smooth* (abbreviated by q -AUS) if there exists $C > 0$ so that $\bar{\rho}_X(t) \leq Ct^q$ for all $t \in [0, 1]$. Let us highlight that the following is proved in [12, Corollary 2.4].

Proposition 2.1. *Let X be a Banach space.*

- (i) *Then $\|\cdot\|_X$ is AUS if and only if $\|\cdot\|_{X^*}$ is AUC^* .*
- (ii) *If $p \in (1, \infty]$ and $q \in [1, \infty)$ are conjugate exponents, then $\|\cdot\|_X$ is p -AUS if and only if $\|\cdot\|_{X^*}$ is q - AUC^* .*

It is worth mentioning that if $X \equiv Z^*$ and the dual norm $\|\cdot\|_{Z^*}$ is AUS, then X must be reflexive (see for instance Proposition 2.6 in [9]). The following proposition is elementary.

Proposition 2.2. *Let X be a Banach space. For any $t > 0$, any weakly null net $(x_\alpha)_\alpha$ in X and any $x \in X \setminus \{0\}$ we have:*

$$\limsup_\alpha \|x + x_\alpha\| \leq \|x\| \left(1 + \bar{\rho}_X \left(\frac{\limsup_\alpha \|x_\alpha\|}{\|x\|} \right) \right).$$

For any weak-null net $(x_\alpha^*)_\alpha \subset X^*$ and for any $x^* \in X^* \setminus \{0\}$ we have*

$$\liminf_\alpha \|x^* + x_\alpha^*\| \geq \|x^*\| \left(1 + \bar{\delta}_X^* \left(\frac{\liminf_\alpha \|x_\alpha^*\|}{\|x^*\|} \right) \right).$$

Assume now that $\varphi: [0, \infty) \rightarrow [0, \infty)$ is an Orlicz function which is 1-Lipschitz and such that $\lim_{t \rightarrow \infty} \varphi(t)/t = 1$. Consider for $(s, t) \in \mathbb{R}^2$,

$$N_2^\varphi(s, t) = \begin{cases} |s| + |s|\varphi(|t|/|s|) & \text{if } s \neq 0, \\ |t| & \text{if } s = 0. \end{cases}$$

The following is proved in [18] (see Lemma 4.3 and its preparation).

Lemma 2.3. *The function N_2^φ is an absolute (or lattice) norm on $\mathbb{R}^2$, meaning that $N_2^\varphi(s_1, s_2) \leq N_2^\varphi(t_1, t_2)$, whenever $|s_i| \leq |t_i|$ for all $i \leq 2$.*

When X is a Banach space, it is easy to see that $\bar{\rho}_X$ is a 1-Lipschitz Orlicz function such that $\lim_{t \rightarrow \infty} \bar{\rho}_X(t)/t = 1$. Thus, one can consider the norm $N_2^{\bar{\rho}_X}$. We will use in the sequel the following reformulation of Proposition 2.2 in terms of the norm $N_2^{\bar{\rho}_X}$.

Lemma 2.4. *Let X be a Banach space. If $(x_\alpha)_\alpha \subset X$ is weakly-null and $x \in X$, then*

$$\limsup_\alpha \|x + x_\alpha\| \leq N_2^{\bar{\rho}_X}(\|x\|, \limsup_\alpha \|x_\alpha\|).$$

Proof. If $x = 0$ there is nothing to do, so we may assume that $x \neq 0$. By application of Proposition 2.2 we see that

$$\limsup_\alpha \|x + x_\alpha\| \leq \|x\| \left(1 + \bar{\rho}_X \left(\frac{\limsup_\alpha \|x_\alpha\|}{\|x\|} \right) \right) = N_2^{\bar{\rho}_X}(\|x\|, \limsup_\alpha \|x_\alpha\|)$$

□

Example 2.5. Let us recall the asymptotic moduli for some classical spaces, mostly taken from [26].

- Let $1 \leq p < \infty$. If $X = (\sum_{n=1}^\infty E_n)_p$, where $\dim(E_n) < \infty$, then $\bar{\delta}_X(t) = \bar{\rho}_X(t) = (1 + t^p)^{1/p} - 1$ for all $t > 0$.
- For any infinite set Γ and $1 \leq p < \infty$, $\bar{\delta}_{\ell_p(\Gamma)}(t) = \bar{\rho}_{\ell_p(\Gamma)}(t) = (1 + t^p)^{1/p} - 1$ for all $t > 0$.
- For any infinite set Γ , $\bar{\delta}_{c_0(\Gamma)}(t) = \bar{\rho}_{c_0(\Gamma)}(t) = \max\{0, t - 1\}$ for all $t > 0$.
- Let J be the James space. Then $\bar{\delta}_J(t) = \bar{\rho}_J(t) = (1 + t^2)^{1/2} - 1$ for all $t > 0$.

- If X has a Schauder basis $(e_n)_{n=1}^\infty$ which satisfies a lower (resp. upper) ℓ_p -estimate with constant one, then $\bar{\delta}_X(t) \geq (1+t^p)^{1/p} - 1$ (resp. $\bar{\rho}_X(t) \leq (1+t^p)^{1/p} - 1$). For instance, the p -convexified Tsirelson space T^p (see [8]) and the Lorentz sequence space $d(w, p)$ satisfy an upper ℓ_p -estimate with constant 1 [24, p. 177]. Moreover, $d(w, p)$ contains almost isometric copies of ℓ_p so $\bar{\rho}_{d(w, p)}(t) = (1+t^p)^{1/p} - 1$ for all $t > 0$.

3. PROOF OF THE MAIN RESULTS

Let us begin with the proof of our main theorem.

Theorem 3.1. *Let X, Y be Banach spaces. Assume that for every $t > 0$, $\bar{\delta}_{X^*}^*(t) \geq \bar{\rho}_Y(t)$ and, for all $t \geq 1$, either $\bar{\delta}_{X^*}^*(t) > \bar{\rho}_Y(t)$ or $\bar{\rho}_Y(t) > t - 1$. Then,*

- (1) *the pair (X^*, Y) has the weak*-to-weakMP.*
- (2) *If moreover $Y \equiv Z^*$ is a dual space, then the pair (X^*, Z^*) has the weak*-to-weak* MP.*
- (3) *If $\bar{\delta}_{X^*}^*(t) = t$ then (X^*, Y) has the W^* MP for any Banach space Y .*

In particular, if X is reflexive then the pair (X^, Y) has the WMP.*

Proof. We will only prove the first assertion since the proof of the second and third one are very similar (replacing the weak topology in Y by the weak* topology in Y).

Let $T: X^* \rightarrow Y$ be a bounded operator which is weak*-to-weak continuous. Without loss of generality, we may assume that T has norm 1. Let (x_n) be a normalized maximizing sequence in X^* which is not weak*-null. Let (x_α) be a subnet which is weak* convergent to $x \neq 0$. By extracting a subnet again, we may assume that $\lim_\alpha \|x_\alpha - x\|$ and $\lim_\alpha \|Tx_\alpha - Tx\|$ exists. Since T is weak*-to-weak continuous, we have that $Tx_\alpha \xrightarrow{w} Tx$. Using Lemma 2.4, we thus have the following estimates:

$$\begin{aligned} 1 &= \|T\| = \lim_\alpha \|Tx_\alpha\| = \lim_\alpha \|Tx + Tx_\alpha - Tx\| \\ &\leq N_2^{\bar{\rho}_Y}(\|Tx\|, \lim_\alpha \|Tx_\alpha - Tx\|). \end{aligned}$$

Now notice that (we use Lemma 2.3)

$$\begin{aligned} N_2^{\bar{\rho}_Y}(\|Tx\|, \lim_\alpha \|Tx_\alpha - Tx\|) &\leq N_2^{\bar{\rho}_Y}(\|x\|, \lim_\alpha \|Tx_\alpha - Tx\|) \\ &\leq N_2^{\bar{\rho}_Y}(\|x\|, \lim_\alpha \|x_\alpha - x\|), \end{aligned}$$

but also

$$\begin{aligned} N_2^{\bar{\rho}_Y}(\|Tx\|, \lim_\alpha \|Tx_\alpha - Tx\|) &\leq N_2^{\bar{\rho}_Y}(\|Tx\|, \lim_\alpha \|x_\alpha - x\|) \\ &\leq N_2^{\bar{\rho}_Y}(\|x\|, \lim_\alpha \|x_\alpha - x\|). \end{aligned}$$

Since $x \neq 0$, we deduce from the definition of $N_2^{\bar{\rho}_Y}$ the following estimates:

$$\begin{aligned} N_2^{\bar{\rho}_Y}(\|x\|, \lim_\alpha \|x_\alpha - x\|) &\leq \|x\| + \|x\| \bar{\rho}_Y\left(\frac{\lim_\alpha \|x_\alpha - x\|}{\|x\|}\right) \\ &\leq \|x\| + \|x\| \bar{\delta}_{X^*}^*\left(\frac{\lim_\alpha \|x_\alpha - x\|}{\|x\|}\right) \\ &\leq \lim_\alpha \|x + x_\alpha - x\| \\ &= 1. \end{aligned}$$

This implies that all the previous inequalities are in fact equalities, in particular

$$N_2^{\bar{\rho}_Y}(\|Tx\|, \lim_\alpha \|x_\alpha - x\|) = N_2^{\bar{\rho}_Y}(\|x\|, \lim_\alpha \|x_\alpha - x\|) = 1 = N_2^{\bar{\rho}_Y}(0, 1).$$

This means that the points $(\|Tx\|, \lim_\alpha \|x_\alpha - x\|)$, $(\|x\|, \lim_\alpha \|x_\alpha - x\|)$ and $(0, 1)$ are aligned in $\mathbb{R}^2$. If $\|Tx\| = \|x\|$ or $\lim_\alpha \|x - x_\alpha\| = 0$, then T attains its norm at x and we are done. Otherwise, it follows that $\lim_\alpha \|x_\alpha - x\| = 1$ and

$$1 = N_2^{\bar{\rho}_Y}(\|x\|, 1) = \|x\| + \|x\|\bar{\rho}_Y(1/\|x\|) = \|x\| + \|x\|\bar{\delta}_{X^*}^*(1/\|x\|).$$

That is, $\bar{\delta}_{X^*}^*(\frac{1}{\|x\|}) = \bar{\rho}_Y(\frac{1}{\|x\|}) = \frac{1}{\|x\|} - 1$, which contradicts our assumptions. $\square$

Remark 3.2. Take $X = \mathbb{R} \oplus_\infty \ell_2$ and $Y = c_0$. Then $\bar{\delta}_X(t) = \max\{0, t - 1\} = \bar{\rho}_Y(t)$ for all $t > 0$. However, the operator $T: X \rightarrow Y$ given by $T((0, e_n)) = \frac{n}{n+1}e_n$ and $T((1, 0)) = 0$ does not attain the norm and admits the non-weakly null maximizing sequence $(x_n)_{n=1}^\infty$ given by $x_n = (1, e_n)$. Thus, the pair (X, Y) fails the WMP.

Remark 3.3. Since $\bar{\rho}_Y$ is 1-Lipschitz and $\bar{\rho}_Y(t) \leq \max\{0, t - 1\}$, the condition $\bar{\rho}_Y(1) = 0$ is equivalent to $\bar{\rho}_Y(t) = \max\{0, t - 1\}$ for all $t > 0$. These spaces are called metric weak* Kadec-Klee spaces. In the separable case, they are precisely those spaces which are $(1 + \varepsilon)$ -isomorphic to a subspace of c_0 , for every $\varepsilon > 0$ [15].

As a direct consequence we obtain that for a special class of Banach spaces, namely the dual ones X^* with $Sz(X) = \omega$ (where ω stands for the first countable ordinal), one can find an equivalent norm $|\cdot|$ on X^* and a Banach space Y such that the pair $((X^*, |\cdot|), Y)$ has the weak*-to-weak*MP. By $Sz(X)$ we mean the Szlenk index of X ; we refer to [23] for its definition, basic properties as well as its main applications to the geometry of Banach spaces.

Corollary 3.4. *If X is separable with $Sz(X) = \omega$, then there exists an equivalent norm $|\cdot|_{X^*}$ on X^* and $q \geq 1$ such that the pair $((X^*, |\cdot|_{X^*}), \ell_q)$ has the weak*-to-weak*MP.*

In particular if $X \equiv Z^$ is a separable reflexive space with $Sz(Z) \leq \omega$, then there exists an equivalent norm on X and there exists $q \geq 1$ such that the pair (X, ℓ_q) has the WMP.*

Proof. Let us start by recalling the fundamental renorming result for spaces with Szlenk index equal to ω . The result is due to H. Knaust, E. Odell and Th. Schlumprecht [21, Corollary 5.3]: if X is a separable Banach space such that $Sz(X) = \omega$, then there exists $p \in (1, \infty)$ such that X^* admits an equivalent p -AUC* norm $|\cdot|$, moreover $\bar{\delta}_{|\cdot|}^*(t) \geq (1 + t^p)^{\frac{1}{p}} - 1$. Let us consider $q > p$. As we already mentioned in Example 2.5, $\bar{\rho}_{\ell_q}(t) = (1 + t^q)^{\frac{1}{q}} - 1$. Thus for every $t > 0$ we have that $\bar{\delta}_{|\cdot|}^*(t) > \bar{\rho}_{\ell_q}(t)$. The result now readily follows from Theorem 3.1. $\square$

The next result follows the idea of [28, Theorem 2], where the same is obtained in the case $X^* = \ell_p$, $Y = \ell_q$, $p \neq q$.

Corollary 3.5. *Let X, Y be Banach spaces. Assume that X is separable and $\bar{\delta}_{X^*}^*(t) > \bar{\rho}_Y(t)$ for all $t > 0$. Let $T: X^* \rightarrow Y$ be a weak*-to-weak continuous operator. Then any non-weak* null maximizing sequence for T has a convergent subsequence.*

Proof. Let $(x_n)_{n=1}^\infty \subset S_{X^*}$ be a non-weak* null maximizing sequence for T . By extracting a subsequence, we may assume that (x_n) is weak* convergent to $x \neq 0$ and the limit $\lim_n \|x_n - x\|$ exists. The proof of Theorem 3.1 shows that T attains its norm at x , and moreover

$$\bar{\rho}_Y\left(\frac{\lim_n \|x_n - x\|}{\|x\|}\right) = \bar{\delta}_{X^*}^*\left(\frac{\lim_n \|x_n - x\|}{\|x\|}\right).$$

Thus $\lim_n \|x_n - x\| = 0$. $\square$

We will now turn to the case when the modulus of asymptotic uniform smoothness of X is bounded above by the modulus of asymptotic uniform convexity of Y . To this aim, we will need the following two lemmata.

Lemma 3.6 (Proposition 2.3 in [17]). *Let X, Y be Banach spaces. If there exists $t > 0$ such that $\bar{\rho}_X(t) < \bar{\delta}_Y(t)$ then every linear operator from X to Y is compact.*

The next one is classical and easy to prove.

Lemma 3.7. *Let X, Y be Banach spaces and let τ_Y be any Hausdorff topology on Y which is coarser than the norm topology. If $T: X^* \rightarrow Y$ is a compact operator which is weak*-to- τ_Y continuous, then T attains its norm.*

Proof. Let (x_α^*) be a net in S_{X^*} such that $\lim_\alpha \|Tx_\alpha^*\| = \|T\|$, we may assume that (x_α^*) is weak*-convergent to $x^* \in B_{X^*}$. Then (Tx_α^*) is τ_Y -convergent to Tx^* . Since the norm topology and τ_Y agree on the norm-compact set $\overline{T(B_{X^*})}$, we have that $\|T\| = \lim_\alpha \|Tx_\alpha^*\| = \|Tx^*\|$. $\square$

We are now ready to prove the desired theorem.

Theorem 3.8. *Let X, Y be Banach spaces and $|\cdot|$ be an equivalent norm on X^* . If there exists $t > 0$ such that $\bar{\rho}_{|\cdot|}(t) < \bar{\delta}_Y(t)$, then*

- (1) *the pair (X^*, Y) has the weak*-to-weakMP.*
- (2) *If moreover $Y \equiv Z^*$ is a dual space, then (X^*, Z^*) has the weak*-to-weak*MP.*

In particular, if X is reflexive then (X^, Y) has the WMP.*

Proof. We only prove the first assertion, the proof of the second one is similar and the last statement is quite obvious. Thanks to Lemma 3.6, we know that every bounded linear operator from $(X^*, |\cdot|)$ to Y is compact. Since $|\cdot|$ is an equivalent norm on X^* , this readily implies that every bounded linear operator from X^* to Y is compact. According to Lemma 3.7, we deduce that every weak*-to-weak continuous operator from X^* to Y attains its norm. $\square$

We highlight some consequences of the previous theorems for particular spaces. In all the cases the proof follows from Theorem 3.1 or Theorem 3.8 and Example 2.5.

Corollary 3.9. *Any of the following conditions ensues that the pair (X, Y) has the WMP:*

- a) *X is a reflexive AUS space (e.g. $X = \ell_p$, T^p , or $d(w, p)$, $1 < p < \infty$), and $Y = \ell_1$.*
- b) *X is a reflexive AUC space (e.g. $X = \ell_p$) and $Y = c_0$.*
- c) *$X = \ell_p$, and either $Y = \ell_q$, $1 < p, q < \infty$, or $Y = J$, the James space.*
- d) *$X = \ell_p$ and either $Y = T^q$ or $Y = d(w, q)$ where $1 < p \leq q < \infty$.*

4. APPLICATION TO SOME CLASSICAL BANACH SPACES

4.1. Dunford–Pettis spaces. We recall that a Banach space Y has the Dunford–Pettis property if and only if for every sequence $(y_n)_n$ in Y converging weakly to 0 and every sequence $(y_n^*)_n$ in Y^* converging weakly to 0, the sequence of scalars $(y_n^*(y_n))_n$ converges to 0. In particular, Schur spaces have it. Classical spaces with the Dunford–Pettis property include as c_0 , $\mathcal{C}(K)$ spaces (where K is a compact Hausdorff space) and $L_1(\mu)$ (where μ is a σ -finite measure), see e.g. [11]. However reflexive spaces never have it.

Lemma 4.1. *Assume that X is reflexive and that Y has the Dunford–Pettis property. Let $T: X \rightarrow Y$ be a bounded operator. Then the following are equivalent:*

- (i) *There exists a non-weakly null maximizing sequence for T .*

(ii) *There exists a non-weakly null maximizing sequence for T^* .*

Proof. First of all, if $(x_n)_n \subset X$ is a maximizing sequence for T , we define $(y_n^*)_n \subset S_{Y^*}$ so that $y_n^*(Tx_n) > \|Tx_n\| - \frac{1}{n}$. It is easy to see that

$$\|T^*y_n^*\| \geq |y_n^*(Tx_n)| > \|Tx_n\| - \frac{1}{n},$$

and taking the limit $n \rightarrow \infty$ we obtain $\lim_{n \rightarrow \infty} \|T^*y_n^*\| \geq \|T\|$. Since $\|T^*\| = \|T\|$ we deduce that $(y_n^*)_n$ is a maximizing sequence for T^* . We use the exact same argument to build a maximizing sequence for T starting from one for T^* .

Now let $T: X \rightarrow Y$ be an operator and let $(x_n)_n$ be a non-weakly null maximizing sequence for T . By weak-compactness, we may extract a subsequence (still denoted the same way) which weakly converges to some x . Now as T is weakly continuous, we have that (Tx_n) weakly converges to Tx . Let $(y_n^*)_n$ be the sequence constructed above. We claim that $(y_n^*)_n$ is not weakly null. Indeed, aiming for a contradiction, assume that $(y_n^*)_n$ is weakly null. As Y has the Dunford–Pettis property, we have that $\lim_{n \rightarrow \infty} y_n^*(Tx_n) = \lim_{n \rightarrow \infty} y_n^*(Tx_n - Tx) = 0$, which contradicts our definition of $(y_n^*)_n$.

The converse is proved in the same way. $\square$

Proposition 4.2. *Let X be a reflexive space and let Y be a Banach space with the Dunford–Pettis property. If (X, Y) has the WMP then any dual operator $T^*: Y^* \rightarrow X^*$ which admits a non-weakly null maximizing sequence attains its norm. In particular the pair (Y^*, X^*) has the weak*-to-weak*MP.*

Proof. let $T^*: Y^* \rightarrow X^*$ be the dual operator of a bounded operator $T: X \rightarrow Y$. Let $(y_n^*)_n$ be a non-weakly null maximizing sequence for T . According to Lemma 4.1, T admits a non-weakly null maximizing sequence. Since (X, Y) has the WMP, T attains its norm at some x . Now using Hahn–Banach theorem, we may pick $y^* \in Y^*$ such that $y^*(Tx) = \|Tx\| = \|T\|$. It is readily seen that the operator T^* attains its norm at y^* . $\square$

Note that the hypothesis “ X is reflexive” in the previous proposition is actually superfluous as the assumption “ (X, Y) has the WMP” already implies that X must be reflexive [5].

We do not know whether the hypothesis on the Dunford–Pettis property is actually needed in the previous result. More precisely:

Question 4.3. Assume that (X, Y) has the WMP. Does it follow that (Y^*, X^*) has the weak*-to-weak*MP?

On the other hand, there are spaces X, Y so that (Y^*, X^*) has the WMP but (X, Y) fails the WMP: just take $Y = \mathbb{R}$ and X any non-reflexive space. We do not know if it is possible to construct such an example in the reflexive case, that is:

Question 4.4. Let X, Y be reflexive spaces so that (Y^*, X^*) has the WMP. Does it follow that (X, Y) has the WMP?

Notice that, under the same conditions as in Proposition 4.2, (X, Y) having the WMP does not imply that (X^{**}, Y^{**}) has the weak*-to-weak*MP (while (Y^*, X^*) does so). Indeed, the next example shows that (ℓ_2, c_0) has the WMP but (ℓ_2, ℓ_∞) fails the weak*-to-weak*MP. It was also suggested to us by R. Aron to consider the following variation of the WMP:

Definition 4.5. We say that a pair (X, Y) has the bidual WMP if for every operator $T: X \rightarrow Y$, the existence of a non weakly-null maximizing sequence for T implies that $T^{**}: X^{**} \rightarrow Y^{**}$ attains its norm.

It is obvious from the definitions that if (X^{**}, Y^{**}) has the weak*-to-weak*MP then (X, Y) has the bidual WMP. However, the next example shows in particular that the converse does not hold in general.

Example 4.6. First of all, notice that (ℓ_2, c_0) has the WMP thanks to Corollary 3.9 b), thus it also has the bidual WMP. Moreover, ℓ_2 is reflexive and c_0 has the Dunford-Pettis property so that Proposition 4.2 implies that (ℓ_1, ℓ_2) has the weak*-to-weak*MP (even the W*MP, see Corollary 4.8). Next, we will prove that (ℓ_2, ℓ_∞) fails the weak*-to-weak*MP (and consequently also fails the WMP and the W*MP).

Let $T : \ell_2 \rightarrow \ell_\infty$ defined for every $x = (x_n)_n \in \ell_2$ by

$$Tx = \left(x_1, x_1 + \left(1 - \frac{1}{2}\right)x_2, x_1 + \left(1 - \frac{1}{3}\right)x_3, \dots, x_1 + \left(1 - \frac{1}{n}\right)x_n, \dots \right).$$

In other words, $Te_1 = \mathbb{1}$ (the constant equal to 1 sequence) and $Te_n = (1 - \frac{1}{n})e_n$. Our claim follows from the items below:

- $\|T\| = \sqrt{2}$. Indeed,

$$\begin{aligned} \|Tx\|_\infty &= \sup \{ |x_1 + (1 - 1/n)x_n| : n \geq 1 \} \\ &\leq \sup \{ (|x_1|^2 + |x_n|^2)^{1/2} (1 + (1 - 1/n)^2)^{1/2} : n \geq 2 \} \\ &\leq \sqrt{2}\|x\|_2. \end{aligned}$$

Moreover,

$$\left\| T \left(\frac{1}{\sqrt{2}}(e_1 + e_n) \right) \right\| \rightarrow \sqrt{2},$$

so $\|T\| = \sqrt{2}$ the sequence $(\frac{1}{\sqrt{2}}(e_1 + e_n))_n$ is a normalized maximizing sequence which is not weakly* null (it weakly* converges to $\frac{1}{\sqrt{2}}e_1$).

- T is weak*-to-weak*-continuous: one can easily check that $T = S^*$ where $S : \ell_1 \rightarrow \ell_2$ is given by $Sx = (\sum_{n=1}^\infty x_n)e_1 + \sum_{n=1}^\infty (1 - 1/n)x_ne_n$.
- T does not attain its norm: if $\|Tx\|_\infty = \sqrt{2}$ for some x with $\|x\|_2 = 1$, then the above estimation implies that $\limsup_n (|x_1|^2 + |x_n|^2)^{1/2} = 1$. Thus $|x_1| = 1$, which implies that $x = \pm e_1$, a contradiction.

4.2. The case of ℓ_1 and Schur spaces. Recall that a Banach space Y is said to have the Schur property if every weakly convergent sequence is also norm-convergent. First of all, let us point out that Schur spaces are the best range spaces for the WMP as this is shown by the next result.

Proposition 4.7. *If X is reflexive and Y is Schur, then (X, Y) has the WMP.*

Proof. Let $T : X \rightarrow Y$ be an operator and let $(x_n)_n$ be a non-weakly null maximizing sequence for T . By weak-compactness, we may extract a subsequence (still denoted the same way) which weakly converges to some $x \in B_X$. Since T is weakly continuous, $(Tx_n)_n$ weakly converges to Tx . Since Y has the Schur property, $(Tx_n)_n$ actually converges to Tx in the norm topology. The fact that $\lim_{n \rightarrow \infty} \|Tx_n\| = \|T\|$ readily implies that $\|Tx\| = \|T\|$. $\square$

It is well known that $\ell_1 \equiv c_0^*$ is weak* asymptotically uniformly convex with modulus $\bar{\delta}_{\ell_1}^*(t) = t$, and the same is true for Z^* instead of ℓ_1 whenever Z is a subspace of c_0 . Consequently, the next result is a direct consequence of Theorem 3.1. Let us mention that if a dual Banach space $X \equiv Z^*$ has modulus $\bar{\delta}_X^*(t) = t$, then Z is asymptotically uniformly flat (that is there exists $t_0 > 0$ such that for every

$t < t_0$, $\bar{\rho}_Z(t) = 0$). This is actually equivalent to the fact that Z is isomorphic to a subspace of c_0 (see [17, Theorem 2.9]).

Corollary 4.8. *If Z is a closed subspace of c_0 , then the pair (Z^*, Y) has the W^*MP for every Banach space Y .*

In particular (ℓ_1, Y) has the W^*MP for every Banach space Y .

However, the previous result is not true anymore if one replaces ℓ_1 by any dual space with the Schur property as this is shown by the following example. It also shows that the W^*MP is not an isomorphic property.

Example 4.9. There exists a dual space $Z = X^*$ with the Schur property such that the pair $(X^*, \mathbb{R})$ fails the W^*MP . In fact Z is going to be the Lipschitz-free space $\mathcal{F}(M)$ where $M = \{0\} \cup \{x_n : n \in \mathbb{N}\} \subset c_0$ is the pointed metric space given by $x_1 = 2e_1$, and $x_n = e_1 + (1 + \frac{1}{n})e_n$ for $n \geq 2$, where (e_n) is the canonical basis of c_0 . Then it is known [19] that $\mathcal{F}(M)$ has the Schur property as M is uniformly discrete and bounded (it is actually isomorphic to ℓ_1) and it is also known [14, Example 5.6] that $\mathcal{F}(M) \equiv X^*$ where

$$X = \{f \in \text{Lip}_0(M) : \lim_{n \rightarrow \infty} f(x_n) = \frac{1}{2}f(x_1)\}.$$

It is readily seen that the sequence $((1 + \frac{1}{n})^{-1}\delta(x_n))_n$ weak* converges to $\frac{1}{2}\delta(x_1) \neq 0$. Now let $f : M \rightarrow \mathbb{R}$ be the Lipschitz map defined by $f(0) = f(x_1) = 0$ and $f(x_n) = 1$ for every $n \geq 2$. It is obvious that $\|f\|_L = \lim_{n \rightarrow \infty} \frac{f(x_n) - f(0)}{d(x_n, 0)} = 1$. Now using the linearization property of free spaces, we may consider the bounded operator $\bar{f} : \mathcal{F}(M) \rightarrow \mathbb{R}$ such that $\bar{f}(\delta(x_n)) = f(x_n)$. Observe that $((1 + \frac{1}{n})^{-1}\delta(x_n))_n$ is a maximizing sequence which is not weak*-null. To finish, we just need to show that $\bar{f}$ does not attain its norm. Assume that $\bar{f}(\mu) = 1$ for $\mu = \sum_{n=1}^{\infty} a_n \delta(x_n) \in S_{\mathcal{F}(M)}$. First note that

$$1 = \bar{f}(\mu) = \sum_{n=2}^{\infty} a_n.$$

Let $A = \{n \geq 2 : a_n > 0\}$ and consider the one-Lipschitz function $g : M \rightarrow \mathbb{R}$ given by $g(x_n) = 1$ if $n \in A$ and $g(x_n) = 0$ otherwise. By evaluating the linear extension of g to $\mathcal{F}(M)$ at μ we get $\sum_{n \in A} a_n \leq 1$. It follows that $a_n \geq 0$ for all $n \geq 2$. Similarly, by evaluating at the one-Lipschitz function $h : M \rightarrow \mathbb{R}$ given by $h(x_1) = 2$ and $h(x_n) = 1$ we get that $-1 \leq a_1 \leq 0$. Now, we have that

$$\mu = \sum_{n=1}^{\infty} a_n \delta(x_n) = \sum_{n=2}^{\infty} a_n |a_1| (\delta(x_n) - \delta(x_1)) + \sum_{n=1}^{\infty} (1 - |a_1|) a_n \delta(x_n).$$

Finally, consider the one-Lipschitz function $j : M \rightarrow \mathbb{R}$ given by $j(0) = j(x_1) = 0$ and $j(x_n) = 1 + 1/n$. Then,

$$\begin{aligned} 1 = \|\mu\| &\geq \langle \bar{j}, \mu \rangle = \sum_{n=2}^{\infty} a_n |a_1| \left(1 + \frac{1}{n}\right) + \sum_{n=2}^{\infty} (1 - |a_1|) a_n \left(1 + \frac{1}{n}\right) \\ &= \sum_{n=2}^{\infty} a_n \left(1 + \frac{1}{n}\right) = 1 + \sum_{n=2}^{\infty} \frac{a_n}{n}. \end{aligned}$$

Thus, $a_n = 0$ for all $n \geq 2$. Then $\bar{f}(\mu) = 0$, a contradiction.

Notice that the Banach space $\mathcal{F}(M)$ in the previous example is not weak*-AUC: $\frac{1}{2}\delta(x_1)$ is an extreme point of $B_{\mathcal{F}(M)}$ [3] but not a preserved extreme point [2], in particular it does not belong to slices of small diameter.

The following example shows that the weak*-to-weak*MP is not stable by isomorphisms.

Example 4.10. There exists a space X isomorphic to c_0 such that (X^*, ℓ_1) fails the weak*-to-weak*MP. Indeed, let M be the metric space given by $M = \mathbb{N} \cup \{0\}$ where $d(n, 0) = d(n, 1) = 1 + 1/n$ and $d(n, m) = 2 + 1/n + 1/m$ for all $n, m \geq 2$. The same argument as [14, Example 5.6] gives that $\mathcal{F}(M) \equiv X^*$, where

$$X = \{f \in \text{Lip}_0(M) : \lim_{n \rightarrow \infty} f(x_n) = \frac{1}{2}f(x_1)\}.$$

It is easy to check that the map $T: c_0 \rightarrow X$ given by $Tx(1) = x_1$ and $Tx(n) = \frac{1}{2}(x_1 + x_n)$ for $n \geq 2$ satisfies that $\|T\| \leq 1$. Moreover, T is an isomorphism with inverse $R: X \rightarrow c_0$ given by $Rf = f(1)e_1 + \sum_{n \geq 2} (2f(n) - f(1))e_n$. Consider the weak*-to-weak*-continuous operator $T^*: \mathcal{F}(M) \rightarrow \ell_1$. First note that $T^*(\delta(n)) = \frac{1}{2}(e_1 + e_n)$ for $n \geq 2$. Thus, $\|T^*\| = 1$ and the sequence $((1 + \frac{1}{n})^{-1}\delta(n))_n$ is a maximizing sequence for T^* which weak*-converges to $\frac{1}{2}\delta(1) \neq 0$. To finish, we need to check that T^* does not attain its norm. Assume that there is $\mu = \sum_{n=1}^{\infty} a_n \delta(x_n) \in S_{\mathcal{F}(M)}$ is so that $\|T^*\mu\|_1 = 1$. Consider the 1-Lipschitz function $f: M \rightarrow \mathbb{R}$ given by $f(0) = f(1) = 0$ and $f(n) = (1 + \frac{1}{n}) \text{sign}(a_n)$ for $n \geq 2$. Then

$$1 = \|\mu\| \geq \langle \bar{f}, \mu \rangle = \sum_{n \geq 2} |a_n| (1 + \frac{1}{n}).$$

Now, consider the 1-Lipschitz function $g: M \rightarrow \mathbb{R}$ given by $g(0) = 0$, $g(1) = 2$ and $g(n) = 1$ for $n \geq 2$. Then

$$1 = \|\mu\| \geq |\langle \bar{g}, \mu \rangle| = |2a_1 + \sum_{n \geq 2} a_n|.$$

Note that

$$T^*\mu = \left(a_1 + \frac{1}{2} \sum_{n \geq 2} a_n \right) e_1 + \frac{1}{2} a_n e_n$$

and so

$$1 = \|T^*\mu\|_1 = |a_1 + \frac{1}{2} \sum_{n \geq 2} a_n| + \frac{1}{2} \sum_{n \geq 2} |a_n| \leq 1.$$

It follows that $\sum_{n \geq 2} |a_n| = 1 \geq \sum_{n \geq 2} |a_n| (1 + \frac{1}{n})$, a contradiction.

4.3. The case of the James sequence spaces. Let $p \in (1, \infty)$. We now recall the definition and some basic properties of the James space $\mathcal{J}_p$. We refer the reader to [1, Section 3.4] and references therein for more details on the classical case $p = 2$. The James space $\mathcal{J}_p$ is the real Banach space of all sequences $x = (x(n))_{n \in \mathbb{N}}$ of real numbers with finite p -variation and satisfying $\lim_{n \rightarrow \infty} x(n) = 0$. The space $\mathcal{J}_p$ is endowed with the following norm

$$\|x\|_{\mathcal{J}_p} = \sup \left\{ \left(\sum_{i=1}^{k-1} |x(p_{i+1}) - x(p_i)|^p \right)^{1/p} : 1 \leq p_1 < p_2 < \dots < p_k \right\}.$$

This is the historical example, constructed for $p = 2$ by R. C. James, of a quasi-reflexive Banach space which is isomorphic to its bidual. In fact $\mathcal{J}_p^{**}$ can be seen as the space of all sequences $x = (x(n))_{n \in \mathbb{N}}$ of real numbers with finite p -variation, which is $\mathcal{J}_p \oplus \mathbb{R}\mathbf{1}$, where $\mathbf{1}$ denotes the constant sequence equal to 1.

The standard unit vector basis $(e_n)_{n=1}^{\infty}$ ($e_n(i) = 1$ if $i = n$ and $e_n(i) = 0$ otherwise) is a monotone shrinking basis for $\mathcal{J}_p$. Hence, the sequence $(e_n^*)_{n=1}^{\infty}$ of the associated coordinate functionals is a basis of its dual $\mathcal{J}_p^*$. Then the weak topology $\sigma(\mathcal{J}_p, \mathcal{J}_p^*)$ is

easy to describe: a sequence $(x_n)_{n=1}^\infty$ in $\mathcal{J}_p$ converges to 0 in the $\sigma(\mathcal{J}_p, \mathcal{J}_p^*)$ topology if and only if it is bounded and $\lim_{n \rightarrow \infty} x_n(i) = 0$ for every $i \in \mathbb{N}$.

For $x \in \mathcal{J}_p$, we define $\text{supp } x = \{i \in \mathbb{N} : x(i) \neq 0\}$. For $x, y \in \mathcal{J}_p$, we denote: $x \prec y$ whenever $\max \text{supp } x < \min \text{supp } y$.

The detailed proof of the following proposition can be found in [27, Corollary 2.4]. This is a consequence of the following fact: there exists $C \geq 1$ such that $\|\sum_{i=1}^n x_i\|_{\mathcal{J}_p}^p \leq C \sum_{i=1}^n \|x_i\|_{\mathcal{J}_p}^p$, for all $x_1 \prec \dots \prec x_n$ in $\mathcal{J}_p$.

Proposition 4.11. *There exists an equivalent norm $|\cdot|$ on $\mathcal{J}_p$ such that it has the following property: for any $x, y \in \mathcal{J}_p$ such that $x \prec y$, we have that*

$$|x + y|^p \leq |x|^p + |y|^p.$$

In particular, the modulus of asymptotic uniform smoothness of $\widetilde{\mathcal{J}}_p := (\mathcal{J}_p, |\cdot|)$ is $\bar{\rho}_{\widetilde{\mathcal{J}}_p}(t) \leq (1 + t^p)^{\frac{1}{p}} - 1$ for all $t \geq 0$.

There is also a natural weak* topology on $\mathcal{J}_p$. Indeed, the summing basis $(s_n)_{n=1}^\infty$ ($s_n(i) = 1$ if $i \leq n$ and $s_n(i) = 0$ otherwise) is a monotone and boundedly complete basis for $\mathcal{J}_p$. Thus, $\mathcal{J}_p$ is naturally isometric to a dual Banach space: $\mathcal{J}_p = X^*$ with X being the closed linear span of the biorthogonal functionals $(e_n^* - e_{n+1}^*)_{n=1}^\infty$ in $\mathcal{J}_p^*$ associated with $(s_n)_{n=1}^\infty$. Note that $X = \{x^* \in \mathcal{J}_p^*, \sum_{n=1}^\infty x^*(n) = 0\}$. Thus, a sequence $(x_n)_{n=1}^\infty$ in $\mathcal{J}_p$ converges to 0 in the $\sigma(\mathcal{J}_p, X)$ topology if and only if it is bounded and $\lim_{n \rightarrow \infty} (x_n(i) - x_n(j)) = 0$ for every $i \neq j \in \mathbb{N}$.

The next lemma is classical, we include its proof for completeness.

Lemma 4.12. *Let $(x_n)_{n=1}^\infty$ be a weak*-null sequence in $\mathcal{J}_p$. Then, for every $x \in \mathcal{J}_p$, we have*

$$\limsup_{n \rightarrow \infty} \|x + x_n\|^p \geq \|x\|^p + \limsup_{n \rightarrow \infty} \|x_n\|^p.$$

Consequently, the modulus of weak asymptotic uniform convexity of $\mathcal{J}_p$ is given by*

$$\bar{\delta}_{\mathcal{J}_p}^*(t) \geq (1 + t^p)^{\frac{1}{p}} - 1.$$

Proof. Let $x = (x(n))_n \in \mathcal{J}_p$, $(x_n)_{n=1}^\infty$ be a weak*-null sequence and $\varepsilon > 0$ be fixed. Without loss of generality, we may and do assume that $\|x\| = 1$. Let $(p_i)_{i=1}^N \subset \mathbb{N}$ be an increasing family such that

$$1 - \varepsilon \leq \left(\sum_{i=1}^{N-1} |x(p_{i+1}) - x(p_i)|^p \right)^{1/p}.$$

Then there exists $N_1 > p_N$ such that for any increasing finite sequence $(q_i)_{i=1}^k$ with $q_1 \geq N_1$,

$$\left(\sum_{i=1}^{k-1} |x(q_{i+1}) - x(q_i)|^p \right)^{1/p} \leq \eta,$$

where $0 < \eta < \varepsilon$ will be precisely chosen at the end of the proof. Now, since $(x_n)_{n=1}^\infty$ is a weak*-null sequence, it is bounded by some $M > 0$ and there exists $N_2 \in \mathbb{N}$ large enough so that for every $n \geq N_2$ and for any increasing finite sequence $(r_i)_{i=1}^l$ with $r_l < N_1$:

$$\sum_{i=1}^{l-1} |x_n(r_{i+1}) - x_n(r_i)|^p \leq \frac{\eta}{3} \quad \text{and} \quad |x_n(r_l) - x_n(N_1)|^p \leq \eta',$$

where η' is chosen so that $\|x\| - \|y\| \geq \frac{\eta}{3}$ for every $x \in [0, M]$ and $y \in [0, \eta']$ (the map $f(x, y) = |x - y|^p$ is Lipschitz on $[0, M] \times [0, M]$, so $\eta' = \min\{\frac{\eta}{3 \text{Lip}(f)}, M\}$)

does the work). Note also that in such a case one also has

$$\begin{aligned} |x_n(r) - x_n(N_1)|^p &\geq ||x_n(r) - x_n(r_l)| - |x_n(r_l) - x_n(N_1)||^p \\ &\geq |x_n(r) - x_n(r_l)|^p - \frac{\eta}{3}, \end{aligned}$$

for any $r \geq N_1$.

Now, let $n \geq N_2$. It follows from the above estimates that we may find a fixed increasing sequence $(q_i)_{i=1}^k$ with $q_1 \geq N_1$ and

$$\sum_{i=1}^{k-1} |x_n(q_{i+1}) - x_n(q_i)|^p \geq \|x_n\|^p - \eta.$$

Note that $p_N < N_1 \leq q_1$ by construction so that

$$\begin{aligned} (\star) \quad \|x + x_n\|^p &\geq \sum_{i=1}^{N-1} |x(p_{i+1}) - x(p_i) + x_n(p_{i+1}) - x_n(p_i)|^p \\ &\quad + \sum_{i=1}^{k-1} |x(q_{i+1}) - x(q_i) + x_n(q_{i+1}) - x_n(q_i)|^p. \end{aligned}$$

But

$$\begin{aligned} \left(\sum_{i=1}^{N-1} |x(p_{i+1}) - x(p_i) + x_n(p_{i+1}) - x_n(p_i)|^p \right)^{\frac{1}{p}} &\geq \left(\sum_{i=1}^{N-1} |x(p_{i+1}) - x(p_i)|^p \right)^{\frac{1}{p}} - \varepsilon \\ &\geq 1 - 2\varepsilon, \end{aligned}$$

which implies that $\sum_{i=1}^{N-1} |x(p_{i+1}) - x(p_i) + x_n(p_{i+1}) - x_n(p_i)|^p \geq 1 - 2p\varepsilon$.

Similarly, we obtain that

$$\sum_{i=1}^{N-1} |x(q_{i+1}) - x(q_i) + x_n(q_{i+1}) - x_n(q_i)|^p \geq \|x_n\|^p - 2pM\eta.$$

Finally, if we chose $\eta < \min(\varepsilon, \frac{\varepsilon}{M})$, we obtain from $(\star)$ the following last estimate

$$\|x + x_n\|^p \geq 1 + \|x_n\|^p - 4p\varepsilon.$$

□

As an application of Theorem 3.1 and the two previous lemmata, we obtain the following corollary.

Corollary 4.13. *If $1 < p \leq q < \infty$ then $(\mathcal{J}_p, \widetilde{\mathcal{J}}_q)$ has the weak*-to-weak* MP.*

We now turn to an application of Lemma 3.6 and Theorem 3.8.

Corollary 4.14. *If $1 < q < p < \infty$ then every bounded operator from $\mathcal{J}_p$ to $\mathcal{J}_q$ is compact. In particular, the pair $(\mathcal{J}_p, \mathcal{J}_q)$ has the weak*-to-weak* MP.*

Proof. Since $\bar{\rho}_{\widetilde{\mathcal{J}}_p}(t) \leq (1 + t^p)^{1/p} - 1$, $\bar{\delta}_{\mathcal{J}_q}^*(t) \geq (1 + t^q)^{1/q} - 1$ and $\bar{\delta}_{\mathcal{J}_q}(t) \geq \bar{\delta}_{\mathcal{J}_q}^*(t)$, we obtain from Lemma 3.6 that every bounded operator from $\widetilde{\mathcal{J}}_p$ to $\mathcal{J}_q$ is compact. Since $\widetilde{\mathcal{J}}_p$ and $\mathcal{J}_p$ are isomorphic, this yields the same conclusion for every bounded operator from $\mathcal{J}_p$ to $\mathcal{J}_q$. To conclude, Theorem 3.8 (2) provides the fact that the pair $(\mathcal{J}_p, \mathcal{J}_q)$ has the weak*-to-weak* MP. □

Having in mind the previous corollaries, it is quite natural to wonder the following:

Question 4.15. Does the pair $(\mathcal{J}_p, \mathcal{J}_q)$ has the weak*-to-weak* MP for $1 < p \leq q < \infty$?

Remark 4.16. Quite surprisingly, the pair $(\mathcal{J}_2, \mathbb{R})$ fails the W^*MP (but has the weak*-to-normMP thanks to Corollary 4.13). Indeed, consider $T: \mathcal{J}_2 \rightarrow \mathbb{R}$ be the linear operator given by

$$\forall x = (x(j))_{j=1}^\infty \in \mathcal{J}_2, \quad Tx := \frac{-x(1)}{2} + \sum_{j=2}^\infty \frac{x(j)}{j^2}.$$

That is, $T = (\frac{-1}{2}, \frac{1}{2^2}, \frac{1}{3^2}, \dots) \in \mathcal{J}_2^*$. Note that T is not weak* continuous since $T(s_n) \not\rightarrow 0$ while the summing basis (s_n) is weak*-null. Since the standard unit vector basis $(e_n)_{n=1}^\infty$ is monotone and shrinking, it follows that for every $x^{**} \in \mathcal{J}_2^{**}$, $\|x^{**}\|_{\mathcal{J}_2^{**}} = \sup_n \|(x^{**}(e_1^*), x^{**}(e_2^*), \dots, x^{**}(e_n^*), 0, \dots)\|_{\mathcal{J}_2}$ (see e.g. Proposition 4.14 in [13]). Thus, it not hard to prove that any norming functional x^{**} for T is of the form $x^{**} = \frac{1}{\sqrt{(t_2-t_1)^2+t_2^2}}(t_1, t_2, t_2, \dots)$. Consequently, in order to maximize $T(x^{**})$ it suffices to maximize the function

$$g(t_1, t_2) = \frac{\frac{-t_1}{2} + t_2(\frac{\pi^2}{6} - 1)}{\sqrt{(t_2 - t_1)^2 + t_2^2}} = \frac{\frac{-1}{2} \frac{t_1}{t_2} + (\frac{\pi^2}{6} - 1)}{\sqrt{(1 - \frac{t_1}{t_2})^2 + (\frac{t_1}{t_2})^2}}.$$

We set $t = \frac{t_1}{t_2}$ and we are now looking for the maximum of the following one variable map:

$$f(t) = \frac{\frac{-1}{2}t + (\frac{\pi^2}{6} - 1)}{\sqrt{(1-t)^2 + t^2}}.$$

A basic study of the map f shows that it attains its maximum at $t_{max} = \frac{\pi^2-9}{2\pi^2-15}$ (and $f(t_{max}) \simeq 0.66$). To conclude, fix $t_1, t_2 \in \mathbb{R}$ such that $\frac{t_1}{t_2} = t_{max}$ and $\sqrt{(t_2 - t_1)^2 + t_2^2} = 1$. Now for every $n \in \mathbb{N}$ let $x_n \in \mathcal{J}_2$ be such that $x_n(1) = t_1$, $x_n(2) = \dots = x_n(n) = t_2$ and $x_n(j) = 0$ whenever $j > n$ (that is, $x_n = (t_1, t_2, \dots, t_2, 0, \dots)$). Then $(x_n)_{n=1}^\infty$ is a normalized maximizing sequence for T which is not weak*-null. However, it is easy to see that T does not attains its norm (as every element in $\mathcal{J}_2$ is a sequence that converges to 0).

4.4. Orlicz spaces. Given an Orlicz function $\varphi: [0, +\infty) \rightarrow [0, +\infty)$ (that is, φ is a continuous convex unbounded function with $\varphi(0) = 0$), the Orlicz sequence space ℓ_φ is the space of all real sequences $x = (x_n)_{n=1}^\infty$ such that $\sum_{n=1}^\infty \varphi(|x_n|/\lambda) < \infty$. It is a Banach space when equipped with the Luxemburg norm:

$$\|x\|_\varphi = \inf\{\lambda > 0 : \sum_{n=1}^\infty \varphi(|x_n|/\lambda) \leq 1\}.$$

The closed linear span of $\{e_n : n \in \mathbb{N}\}$ in ℓ_φ is denoted h_φ . The space h_φ coincides with ℓ_φ precisely if φ satisfies the Δ_2 condition at zero, i.e. $\limsup_{t \rightarrow 0} \varphi(2t)/\varphi(t) < \infty$. The space h_φ (or ℓ_φ) is reflexive if and only if both φ and φ^* satisfy the Δ_2 condition at zero, where $\varphi^*(t) = \sup\{st - \varphi(s)\}$ is the convex conjugate of φ . The Boyd indices of an Orlicz function φ are defined as follows:

$$\alpha_\varphi = \sup\{p > 0 : \sup_{0 < u, t \leq 1} \frac{\varphi(tu)}{\varphi(u)t^p} < \infty\}, \quad \beta_\varphi = \inf\{p > 0 : \inf_{0 < u, t \leq 1} \frac{\varphi(tu)}{\varphi(u)t^p} > 0\}.$$

It is known that $\beta_\varphi < \infty$ precisely if φ satisfies the Δ_2 condition at 0. The asymptotic moduli of the space h_φ is linked to the Boyd indices: h_φ is AUS (resp. AUC) if and only if $\alpha_\varphi > 1$ (resp. $\beta_\varphi < \infty$). Indeed, h_φ is AUS if and only if $\alpha_\varphi > 1$, and α_φ is the supremum of the numbers α such that $\bar{\rho}_{h_\varphi}$ has power type α

[16]. In addition, β_φ is the infimum of the numbers β such that $\bar{\delta}_{h_\varphi}$ has power type β [7].

In order to apply Theorem 3.1 to the case of Orlicz spaces we need an estimation of $\bar{\rho}_{h_\varphi}(t)$ and $\bar{\delta}_{h_\varphi}(t)$ for all $t > 0$. To this end, consider the following indices:

$$\begin{aligned} p_\varphi &= \sup\{p > 0 : u^{-p}\varphi(u) \text{ is non-decreasing for all } 0 < u \leq \varphi^{-1}(1)\} \\ q_\varphi &= \inf\{p > 0 : u^{-p}\varphi(u) \text{ is non-increasing for all } 0 < u \leq \varphi^{-1}(1)\}. \end{aligned}$$

Clearly $1 \leq p_\varphi \leq q_\varphi \leq \infty$. Moreover, φ (resp. φ^*) satisfies Δ_2 condition at 0 if and only if $q_\varphi < \infty$ (resp. $p_\varphi > 1$), see [25] or [10]. Delphech [10] showed that if $q_\varphi < \infty$ then

$$(1 + t^{q_\varphi})^{1/q_\varphi} - 1 \leq \bar{\delta}_{h_\varphi}(t)$$

for all $t \in (0, 1]$, but actually the proof works for all $t > 0$. Analogously, one can show that

$$\bar{\rho}_{h_\varphi}(t) \leq (1 + t^{p_\varphi})^{1/p_\varphi} - 1$$

for all $t > 0$.

Remark 4.17. In general $[\alpha_\varphi, \beta_\varphi] \subset [p_\varphi, q_\varphi]$, but the inclusion may be strict [25]. Thus the previous inequalities are not tight. Also, recall that, given any $p \in [\alpha_\varphi, \beta_\varphi]$, the space h_φ contains almost isometric copies of ℓ_p . Thus $\bar{\delta}_{\ell_\varphi}(t) \leq (1 + t^{\alpha_\varphi})^{1/\alpha_\varphi} - 1$ and $\bar{\rho}_{\ell_\varphi}(t) \geq (1 + t^{\beta_\varphi})^{1/\beta_\varphi} - 1$ for all $t > 0$.

Corollary 4.18. *Let φ, ψ be Orlicz functions. Assume that h_φ, h_ψ are reflexive and $q_\varphi \leq p_\psi$. Then the pair (h_φ, h_ψ) has the WMP.*

Remark 4.19. Given Orlicz functions φ, ψ , if $\alpha_\varphi > \beta_\psi$, then every operator from h_φ to $h_\psi = \ell_\psi$ is compact [6], and so (h_φ, h_ψ) has the WMP.

4.5. Remarks about the pair (L_p, L_q) . In what follows, L_p stands for $L_p([0, 1])$ with $1 < p < \infty$. It is known (see [26] at page 117 for instance) that if $X = L_p$ then there exist constants $C_1(p), C_2(p)$ such that for $1 < p < 2$ we have

$$\begin{aligned} C_1(p)t^2 &\leq \bar{\delta}_X(t) \leq (p-1)t^2 \\ \frac{1}{p}t^p &\leq \bar{\rho}_X(t) \leq \frac{2}{p}t^p \end{aligned}$$

and for $2 < p < \infty$ we have that

$$\begin{aligned} C_1(p)t^p &\leq \bar{\delta}_X(t) \leq \frac{1}{p}t^p \\ (p-1)t^2 &\leq \bar{\rho}_X(t) \leq C_2(p)t^2. \end{aligned}$$

Consequently, for $1 < p < q < \infty$, we cannot apply Theorem 3.1 to prove that the pair (L_p, L_q) has the WMP. Nevertheless, replacing the weak topology by the topology τ_m of convergence in measure, we can apply similar techniques to prove the following related results.

Proposition 4.20. *Let $1 < p < q < \infty$ and let $T: L_p \rightarrow L_q$ be a bounded operator which is τ_m -to- τ_m continuous. If there exists a maximizing sequence $(x_n)_n \subset L_p$ for T which τ_m -converges to some $x \neq 0$, then T attains its norm at x .*

Proof. The proof follows the same lines as in Theorem 3.1. In fact, L_p has the following property (see [20] e.g.): if $(x_n)_n \subset L_p$ converges to 0 in measure, then for every $x \in L_p$

$$(\star) \quad \limsup_n \|x + x_n\| = (\|x\|^p + \limsup_n \|x_n\|^p)^{1/p}.$$

Let $T: L_p \rightarrow L_q$ be a bounded operator which is τ_m -to- τ_m continuous and let $(x_n)_n \subset L_p$ be a maximizing sequence for T which τ_m -converges to some $x \neq 0$. Without loss of generality, we may assume that T has norm 1. Since T is τ_m -to- τ_m continuous, we have that $Tx_n \xrightarrow[n]{\tau_m} Tx$. Using $(\star)$, we thus have the following estimates:

$$\begin{aligned}
1 &= \|T\| = \lim_n \|Tx_n\| = \lim_n \|Tx + Tx_n - Tx\| \\
&= \left(\|Tx\|^q + \lim_n \|Tx_n - Tx\|^q \right)^{\frac{1}{q}} \\
&\leq \left(\|Tx\|^q + \lim_n \|x_n - x\|^q \right)^{\frac{1}{q}} \\
&\leq \left(\|Tx\|^p + \lim_n \|x_n - x\|^p \right)^{\frac{1}{p}} \\
&= \left(\|Tx\|^p + 1 - \|x\|^p \right)^{\frac{1}{p}}
\end{aligned}$$

Therefore, we deduce that $\|Tx\| \geq \|x\|$, which finishes the proof. $\square$

Now the lack of τ_m -compactness of the unit ball of L_p forces us to consider pairs (X, L_q) where X is a subspace of L_p whose unit ball B_X is τ_m -compact. For instance, it is proved in [20] that X embeds almost isometrically into ℓ_p if and only if B_X is compact for the topology inherited by the L_1 -norm; for those X , B_X is in particular τ_m -compact. To the best of our knowledge, such subspaces haven't been characterized.

Corollary 4.21. *Let $1 < p < q < \infty$. If X is a subspace of L_p such that B_X is τ_m -compact, then the pair (X, L_q) has the τ_m -to- τ_m MP.*

Let us briefly discuss the case when $1 < q < p < \infty$. For the pair (ℓ_p, ℓ_q) , this was handled by Pitts Theorem (or more generally by Theorem 3.8) saying that every operator from ℓ_p to ℓ_q is compact. This approach fails for (L_p, L_q) . Indeed, H. P. Rosenthal characterized in [29, Theorem A.2] when every operator from $L_p(\mu)$ to $L_q(\nu)$ is compact. That is never the case for $L_p[0, 1]$ and $L_q[0, 1]$. However, if $q < p$, $1 \leq q < 2$, then every operator from $L_p[0, 1]$ to ℓ_q is compact, and if $q < p$ and $2 < p$ then every operator from ℓ_p to L_q is compact.

ACKNOWLEDGMENTS

Part of this work was carried out during a visit of the two named authors in Murcia (Spain) in January 2020. They are deeply grateful to Matías Raja and the “Universidad de Murcia” for the hospitality and excellent working conditions there. The authors would like to thank Richard M. Aron for useful conversations.
