ABSTRACT

As a continuation of our interest in the study of triterpenoid saponins from *Albizia zygia*, phytochemical investigation of its stem barks led to the isolation of two new oleanane-type saponins, named zygiasides **C–D** (**1–2**). Their structures were established on the basis of extensive analysis of 1D and 2D NMR (¹H-, ¹³C NMR, DEPT, COSY, TOCSY, ROESY, HSQC and HMBC) experiments, HRESIMS studies, and by chemical evidence as, 3-O-[β-D-glucopyranosyl-(1→2)-[α-L-arabinopyranosyl-(1→6)]-β-D-glucopyranosyl]-21-O-[(2E,6S)-2,6-dimethyl-6-O-(β-D-quinovopyranosyl) octa-2,7-dienoyl]acacic acid 28-O-α-L-arabinofuranosyl-(1→4)-[β-D-glucopyranosyl-(1→3)]-α-L-rhamnopyranosyl-(1→2)-β-D-glucopyranosyl ester (**1**) and 3-O-[β-D-glucopyranosyl-(1→2)-[β-D-fucopyranosyl-(1→6)]-β-D-glucopyranosyl]-21-O-[(2E,6S)-2,6-dimethyl-6-O-(β-D-quinovopyranosyl) octa-2,7-dienoyl]acacic acid 28-O-α-L-arabinofuranosyl-(1→4)-[β-D-glucopyranosyl-(1→3)]-α-L-rhamnopyranosyl-(1→2)-β-D-glucopyranosyl ester (**2**).

1. Introduction

The genus *Albizia* comprises about 150 species widely distributed in the tropics, with the greatest diversity in Africa and South America (Abdel-Kader et al. 2001). Triterpenoid saponins, mainly described in this genus are complex acacic acid glycosides, sharing the same structural features: they all have acacic acid as aglycon unit, oligosaccharide moieties at C-3 and C-28, and an acyl group at C-21. Recently, adianthifoliosides (Haddad et al. 2003, 2004), grandibracteosides (Krief et al. 2005), gummiferaosides (Cao et al. 2007), julibrosides (Liang et al. 2005; Zheng et al. 2006, 2010; Zou et al. 2010), coriariosides (Noté et al. 2009, 2010); albizosides (Liu et al. 2010), and lebbeckosides (Noté et al. 2015) have been reported.

In our previous work, we described the isolation of two acacic acid glycosides, new apoptosis-inducing agents, named zygiaosides A–B from the *n*-BuOH extract of the roots of *Albizia zygia* (DC.) J.F. Macbr (Noté et al. 2016). As part of our continuing study of triterpenoid saponins from this plant, investigation of its stem barks resulted in the isolation of two new acacic acid-type saponins, named zygiaosides C–D (**1–2**). Herein, we report their isolation and structural determination.

2. Results and discussion

The air-dried finely powdered stem bark of *A. zygia* was extracted with EtOH 70% in a Soxhlet apparatus. After evaporation of the solvent, the resulting brown residue was suspended in 70 mL of water and then submitted to column chromatography (CC) using Diaion HP-20 resin yielding four main fractions after TLC monitoring. The crude saponin mixture was then submitted to VLC using silica gel to give five main subfractions. Purification of the eluated subfractions by Semprep-HPLC afforded two new triterpenoid saponins, named zygiaosides C–D (**1–2**) (Figure 1).

Zygiaoside C (**1**) was obtained as a white, amorphous powder. Its high-resolution electrospray ionization mass spectrometry (HRESIMS) (positive-ion mode) exhibited a pseudo-molecular ion peak at m/z 1877.8960 $[M + NH_4]^+$ (calcd 1877.8956), consistent with a molecular formula of $C_{86}H_{138}O_{43}$. Upon acid hydrolysis with 2.0 M HCl, **1** gave an acacic acid lactone unit, which was identified with an authentic sample, together with glucose (Glc), arabinose (Ara), rhamnose (Rha), arabinofuranose (Ara_f), and quinovose (Qui), which were identified by co-TLC with authentic samples. The absolute configuration of these sugar residues was determined to be D for Glc, Qui, and L for Ara, Rha and Ara_f based on GC analysis of their trimethylsilyl thiazolidine derivatives (See Experimental Section) (Chaabi et al. 2010). 1H NMR spectrum of **1** showed seven angular methyl groups as singlets at δ_H 0.97, 1.07, 1.10, 1.16, 1.19, 1.23, and 1.84 (each 3H, s), one olefinic proton at δ_H 5.65 (H-12), one oxygen-bearing methine proton at δ_H 3.24 (H-3), and sugar proton signals between δ_H 3.74–6.30. Its ^{13}C NMR spectrum showed two olefinic carbon signals at δ_C 123.0 and 143.3, suggesting that **1** was an oleanane type triterpenoid saponin. 1D (1H and ^{13}C NMR, DEPT) and 2D (COSY, HSQC and HMBC) NMR techniques permitted the unambiguous assignment of all 1H and ^{13}C NMR signals of the aglycon of **1** identified as acacic acid (3 β , 16 α , 21 β -trihydroxyolean-12-ene-28-oic acid) by comparison of its 1H and ^{13}C NMR signals with those reported in the literature (Table S1) (Noté et al. 2015, 2016).

Substitutions at C-3 and C-28 of acacic acid were evidenced by the observed glycosylation-induced shifts of C-3 at δ_C 89.1 (deshielded signal for C-3 of the aglycon) and C-28 at

Figure 1. Structure of isolated saponins (1–2).

δ_c 174.4 (shielded signal for C-28 of the aglycon). Substitution at C-21 was ascertained from the acylation-induced shift observed for C-21 at δ_c 76.9 (desielded signal for C-21 of the aglycon). All of these data established that **1** was a 21-acyl 3, 28-bidesmosidic acacic acid derivative, sugar chains being linked to C-3 and C-28 through an ether and ester bond, respectively.

Concerning the sugar units, the ^1H NMR spectrum of **1** showed eight anomeric protons at δ_H 4.84 (1H, d, $J = 7.3$ Hz), 4.94 (1H, d, $J = 6.8$ Hz), 5.35 (1H, d, $J = 7.3$ Hz), 6.10 (1H, d, $J = 8.2$ Hz), 5.93 (1H, brs), 6.29 (1H, brs), 5.36 (1H, d, $J = 7.8$ Hz), and 4.90 (1H, d, $J = 7.8$ Hz) which gave correlations in the HSQC spectrum with carbon atom resonances at δ_c 104.9, 105.3, 105.7, 95.6, 101.8, 111.0, 105.9 and 99.3, respectively (Tables S2 and S3). The ^1H and ^{13}C NMR data (Tables S2–S3) of the monosaccharide residues were assigned starting, either from the readily identifiable anomeric proton of each hexosyl or pentosyl unit, or from the CH_3 -proton doublet of each 6-deoxyhexosyl unit, by means of COSY, HSQC-TOCSY, HSQC, NOESY, and HMBC spectra obtained for this compound. Based on the coupling constants of the anomeric protons and the chemical shifts of the anomeric carbons, the anomeric configuration of the sugar moieties were determined as β for the glucose and quinovose moieties and α for arabinose, rhamnose and arabinofuranose moieties.

In addition, the ^1H NMR spectrum of compound **1** exhibited one olefinic proton signal at δ_H 6.94 (1H, t, $J = 7.2$ Hz), and one group of one-substituted olefinic proton signals at δ_H 6.21

(1H, dd, $J = 10.2$; 17.8 Hz), 5.25 (1H, d, $J = 10.2$ Hz) and 5.46 (1H, d, $J = 17.8$ Hz), indicating that compound **1** has one monoterpenoid unit (Table S3) (Liu et al. 2010).

The sequencing of the glycosidic chains was achieved by analysis of HMBC and NOESY experiments. For the oligosaccharide moiety at C-3, connectivity observed in the HMBC spectrum between δ_{H} 4.84 (H-1 GlcI) and δ_{C} 89.1 (C-3 Agly), suggested that this sugar was directly attached to C-3 of the aglycon. This was supported by the NOESY correlation observed between δ_{H} 4.84 (H-1 GlcI) and δ_{H} 3.24 (H-3 Agly). The HMBC correlation observed between δ_{H} 4.94 (H-1 Ara) and δ_{C} 69.7 (C-6 GlcI), allowed us to suggest that Ara was linked to C-6 of GlcI. This was supported by the NOESY correlation observed between δ_{H} 4.94 (H-1 Ara) and δ_{H} 4.26 (H-6a GlcI). Moreover, in the HMBC spectrum, a correlation observed between δ_{H} 5.35 (H-1 GlcII) and δ_{C} 83.0 (C-2 GlcI), indicated that GlcII was linked at C-2 of GlcI. This was confirmed by the NOESY correlation observed between δ_{H} 5.35 (H-1 GlcII) and δ_{H} 4.18 (H-2 GlcI) (Figure 2a). These data are consistent with a triglycosidic chain determined as β -D-glucopyranosyl-(1 $\rightarrow$ 2)-[α -L-arabinopyranosyl-(1 $\rightarrow$ 6)]- β -D-glucopyranosyl unit linked to C-3 of the aglycon.

In addition, extensive analysis of 1D and 2D NMR spectra of **1**, revealed the sugar moiety at C-28 was identical to that of julibrosides J_{16} and J_{17} (Zou et al. 2010), J_{14} and J_{28} (Liang et al. 2005), $J_{32'}$, $J_{35'}$ and J_{36} (Zheng et al. 2006), adianthifoliosides A–F (Haddad et al. 2003, 2004), and coriarioside A (Noté et al. 2009), and the monoterpene-quinovosyl moiety at C-21 was identical to that of adianthifolioside F (Haddad et al. 2004) and prosapogenin-8 (Zheng et al. 2006). Hence, the units attached at C-28 and C-21 of the aglycon of **1** were established as α -L-arabinofuranosyl-(1 $\rightarrow$ 4)-[β -D-glucopyranosyl-(1 $\rightarrow$ 3)]- α -L-rhamnopyranosyl-(1 $\rightarrow$ 2)- β -D-glucopyranoside, and (2E,6S)-2,6-dimethyl-6-*O*-(β -D-quinovopyranosyl)octa-2,7-dienoyl, respectively (Figure 2b and c). Consequently, the structure of zygiasides C (**1**) was determined as 3-*O*-[β -D-glucopyranosyl-(1 $\rightarrow$ 2)-[α -L-arabinopyranosyl-(1 $\rightarrow$ 6)]- β -D-glucopyranosyl]-21-*O*-[(2E,6S)-2,6-dimethyl-6-*O*-(β -D-quinovopyranosyl)octa-2,7-dienoyl] acacic acid 28-*O*- α -L-arabinofuranosyl-(1 $\rightarrow$ 4)-[β -D-glucopyranosyl-(1 $\rightarrow$ 3)]- α -L-rhamnopyranosyl-(1 $\rightarrow$ 2)- β -D-glucopyranosyl ester, a new acacic acid-type saponin.

Compound **2**, obtained as a white amorphous powder, exhibited in its HRESIMS spectrum (positive-ion mode) a pseudo-molecular ion peak at m/z 1895.8614 [$M + \text{Na}$] $^{+}$ (calcd 1895.8661), consistent with a molecular formula of $\text{C}_{87}\text{H}_{140}\text{O}_{43}$. As already observed for **1**, acid hydrolysis of **2** also afforded an acacic acid lactone unit, identified by co-TLC with authentic sample, together with D-glucose, D-fucose, D-quinovose, L-arabinofuranose and L-rhamnose units which were identified by GC analysis of their trimethylsilyl thiazolidine derivatives (See Experimental Section). Comparison of 1D and 2D NMR data of **2** with those of **1** indicated that **2** had also acacic acid as aglycon (Table S1). The observation of glycosylation- and acylation-induced shifts at δ_{C} 89.2 (C-3 Agly), 76.8 (C-21 Agly), and 174.4 (C-28 Agly) in the ^{13}C NMR spectrum of **2** suggested that it should be also a 21-acyl 3,28-bidesmosidic acacic acid derivative with sugar chains linked to C-3 and C-28 through an ether and ester bond, respectively, and with an acyl group attached at C-21. The ^1H NMR spectrum of **2** showed eight anomeric protons signals at δ_{H} 4.83 [1H, d, $J = 7.4$ Hz, glucose (GlcI)], 4.90 [1H, d, $J = 7.8$ Hz, fucose (Fuc)], 5.35 [1H, d, $J = 7.8$ Hz, glucose (GlcII)], 6.09 [1H, d, $J = 7.9$ Hz, glucose (GlcIII)], 5.93 [1H, brs, rhamnose (Rha)], 5.37 [1H, d, $J = 7.7$ Hz, glucose (GlcIV)], 6.30 [1H, brs, arabinofuranose (Araf)], and 4.89 [1H, d, $J = 7.8$ Hz, quinovose (Qui)], which correlated with eight anomeric carbon atom resonances at δ_{C} 105.0, 105.5, 105.7, 95.7, 101.8, 105.9, 111.0, and 99.3, respectively in the HSQC spectrum (Tables S2 and S3). Comparison of the NMR data

Figure 2. Key HMBC and NOESY correlations of compound 1.

of **2** with those of **1** revealed that the units attached at C-21 and C-28 of the aglycon of **2** were identical to those of **1**. Therefore, the units attached at C-21 and C-28 of **2** were established as [(2*E*,6*S*)-2,6-dimethyl-6-*O*-(β -D-quinovopyranosyl)octa-2,7-dienoyl] and α -L-arabinofuranosyl-(1 $\rightarrow$ 4)-[β -D-glucopyranosyl-(1 $\rightarrow$ 3)]- α -L-rhamnopyranosyl-(1 $\rightarrow$ 2)- β -D-glucopyranoside moiety, respectively. However, the oligosaccharide chain at C-3 in **2** was similar to those of **1** except for the appearance of fucopyranosyl signals instead of arabinopyranosyl signals observed in **1**. Extensive analysis of 1D and 2D NMR spectra of **2** allowed us to identify the unit attached at C-3 as β -D-glucopyranosyl-(1 $\rightarrow$ 2)-[β -D-fucopyranosyl-(1 $\rightarrow$ 6)]- β -D-glucopyranoside, a unit identical to that of gummiferaoside C obtained from *Albizia gummifera* (Cao et al. 2007). Thus, the structure of compound **2** was established as 3- *O*-[β -D-glucopyranosyl-(1 $\rightarrow$ 2)

-[β -D-fucopyranosyl-(1 $\rightarrow$ 6)]- β -D-glucopyranosyl]-21-O-[(2*E*,6*S*)-2,6-dimethyl-6-O-(β -D-quinovopyranosyl)octa-2,7-dienoyl]acacic acid 28-O- α -L-arabinofuranosyl-(1 $\rightarrow$ 4)-[β -D-glucopyranosyl-(1 $\rightarrow$ 3)]- α -L-rhamnopyranosyl-(1 $\rightarrow$ 2)- β -D-glucopyranosyl ester, a new acacic acid-type saponin, named *zygiaoside D*.

3. Experimental

3.1. General experimental procedure

Optical rotations were measured on a Jasco P-2000 polarimeter. ^1H NMR (600 MHz) and ^{13}C NMR (150 MHz) spectra were recorded at room temperature in pyridine- d_5 using a Bruker 600 MHz spectrometer. Chemical shifts are given in δ (ppm) value relative to TMS as internal standard. HRESIMS spectra were recorded on a microTOF ESI-TOF mass spectrometer (Agilent) operating in positive mode. Analytical HPLC was performed on Varian 920-LC apparatus equipped with an autosampler, a pump, a diode array detector (DAD), and Galaxie software. Semipreparative HPLC was performed on a Gilson apparatus equipped with Trilution LC software using a Nucleodur 100-5 C18ec (21 $\times$ 250 mm, 5 μm) column purchased from Machery-Nagel (Germany). Thin layer chromatography (TLC) was performed on precoated silica gel plates (60 F_{254} , Merck) using the system solvent *n*-BuOH-AcOH- H_2O , 65:15:25 as eluent. The spots were observed after spray with Komarowsky reagent, which is a mixture (5:1) of *para*-hydroxybenzaldehyde (2% in MeOH) and Ethanolic H_2SO_4 (50%). Column chromatography (CC) was carried out using Diaion HP-20 resin, and Vacuum-liquid chromatography (VLC) using silica gel 60 (15–40 and 40–63 μm).

3.2. Plant material

The stem barks of *A. zygia* were harvested at Nkolbisson, Yaoundé peripheral quarter, in Cameroon in November 2013 under the guidance of Mr. Victor Nana, botanist of the National Herbarium of Cameroon (NHC), where a voucher specimen (2339/SRFK) was deposited.

3.3. Extraction and isolation

Air-dried finely powdered stem barks (100 g) of *A. zygia* were extracted with EtOH 70% in a Soxhlet apparatus. This hydroalcoholic solution was then evaporated to dryness under reduced pressure to give a dark residue (8.0 g). This residue was suspended in 70 mL of water and then submitted to column chromatography (CC) using Diaion HP-20 resin, eluting with H_2O , 50% MeOH, 70% MeOH, 80% MeOH, 90% MeOH, and 100% MeOH, successively giving four main fractions (ZE1–ZE4) after TLC monitoring. The 80% MeOH fraction (ZE3) was evaporated to dryness yielding a crude saponin mixture (1.449 g) that was then submitted to VLC using silica gel 60 (15–40 μm), eluted with CH_2Cl_2 -MeOH (80:20) and CH_2Cl_2 -MeOH- H_2O (70:30:5, 60:32:6.5) to give five main subfractions (ZE31–ZE35). Subfraction ZE35 (255.6 mg) was purified by semipreparative HPLC using gradient system of CH_3CN - H_2O (20 mL/min) to yield compounds **1** (t_{R} , 5.30 min, 7.3 mg) and **2** (t_{R} , 5.90 min, 8.0 mg).

3.4. Acid hydrolysis and GC Analysis

Each saponin (2 mg) was hydrolyzed with 2 mL of 2 M HCl at 85 °C during 2 h. After cooling, the solvent was removed under reduced pressure. The sugar mixture was extracted from the aqueous phase (10 mL) and washed with CH₂Cl₂ (3 × 5 mL). Combined CH₂Cl₂ extracts were washed with water to give after evaporation the aglycon moiety, which was compared with authentic standard sample by Co-TLC. The sugars were first analyzed by TLC over silica gel (CHCl₃–MeOH–H₂O, 8:5:1) by comparison with standard samples. The absolute configuration of each monosaccharide was determined from GC–MS analysis of their trimethylsilylated derivatives by comparison with authentic samples using the method previously described (Chaabi et al. 2010). The following sugars were detected: D-glucose, D-fucose, D-quinovose, L-arabinose, L-arabinofuranose and L-rhamnose.

(Overlapped proton NMR signals are reported without designated multiplicity).

4. Conclusions

This study unveiled the presence of two new triterpenoid saponins from the stem barks of *A. zygia*. In comparison with the previous isolated triterpenoid saponins from the roots of the same plant, they share the same structural features: they all have acacic acid as aglycon unit, oligosaccharide moieties at C-3 and C-28, and an acyl group at C-21, differing only by the nature, number, and the substitution pattern of the oligosaccharide moieties attached at C-3 and C-28, and by the length of the Monoterpene-quinovosyl moiety at C-21, which are all known as acacic acid-type saponins (AATS) (Lacaille-Dubois et al. 2011). *A. zygia* may therefore be considered as a potential rich source of this type of complex saponins. Nevertheless, further studies are necessary to support this conclusion, especially the search of this type of triterpenoid saponins from the leaves of this species.

Acknowledgments

The authors are also grateful to Mr Victor Nana of the *National Herbarium of Cameroon* (NHC) for the identification and collection of plant.

Disclosure statement

No potential conflict of interest was reported by the authors.

Funding

This work was supported by the Agence Universitaire de la Francophonie (AUF) [grant number DRACGL-2017–007] (Joséphine Ngo Mbing).
