Abstract: We report a molecular design and concept using π -system elongation and steric effects from helicenes surrounding a triphenylene core toward stable chiral polycyclic aromatic hydrocarbons (PAHs) with a maximal π -distortion to tackle their aromaticity, supramolecular and molecular properties. The selective syntheses, and the structural, conformational and chiroptical properties of two diastereomeric large multi-helicenes of formula $C_{90}H_{48}$ having a triphenylene core and embedding three [5]helicene units on their inner edges and three [7]helicene units at their periphery are reported based on diastereoselective and, when applicable, enantiospecific (!) Yamamoto-type cyclotrimerizations of racemic or enantiopure 9,10-dibromo[7]helicene. Both molecules have an extremely distorted triphenylene core, and one of them exhibits the largest torsion angle recorded so far for a benzene ring (twist = 36.9°). The analysis of aromaticity distribution in these model molecules using magnetic criteria revealed a non-aromatic character of their triphenylene cores and provides a new look at aromaticity in three-dimensional PAHs. One diastereomer can complex up to three silver(I) ions in the bay region (cavities) of its peripheral [7]helicene units, opening the door to chiral cationic metal-nanographene hybrids.

Introduction

Two-dimensional polycyclic aromatic hydrocarbons (PAHs) are diverse in sizes and shapes, starting from small naphthalene or triphenylene units to graphene sheets and/or flakes having both dimensions larger than 100 nm. Large PAHs can exhibit exceptional electronic and physical properties governed by their

size and the nature of their periphery. Thus, considerable efforts are currently underway to synthesize well-defined large 2D PAHs such as graphene nanoribbons and nanographenes by organic synthesis (bottom-up approach) in solution or on a surface and to investigate their properties and applications.^[1] Because PAHs are somewhat flexible and stretchable molecules, it allows the design of curved PAHs such as bowls, saddles, coiled ribbons, propellers and circular belts with defined molecular chirality.^[2] The latter property is of a great interest in life, chemical, and physical sciences as well as technology, because it allows an additional tuning of molecular properties and functions for many applications.^[3] Large chiral PAHs have thus become molecules of utmost interest as three-dimensional chiral nanographenes, and small curved PAHs are now often sought as building blocks for their construction in the racemic series.^[4] In that direction, multi-helicenes have emerged as a class of promising well-defined large chiral PAHs.^[5] Multi-helicenes can exist as several diastereomers, each existing as a pair of enantiomers (except in the cases of some achiral *meso* diastereomers), that can more or less rapidly interconvert depending on the torsional energy and flexibility of the molecules. The proper accumulation of helical strain in multi-helicenes can produce exceptionally distorted molecules showing some benzene units suffering from an extreme torsion angle. For instance, record torsions of 35.3° and 35.7° were recently measured in a D_2 -symmetric quadruple helicene^[6] and a C_2 -symmetric hextuple helicene,^[7] respectively. A fruitful approach to racemic triple helicenes and higher order congeners was based on cyclotrimerization reactions to forge a distorted triphenylene core.^[7,8] Using this approach, we report herein the diastereoselective and, when applicable, enantiospecific syntheses of two large and extremely distorted diastereomeric hextuple helicenes of formula $C_{90}H_{48}$. The conformational behavior, the structure, the chiroptical properties and the torsion-induced deficient local aromaticity in these molecules are discussed in detail, together with the exploration of the complexation ability toward silver(I) ions for one of them.

Results and Discussion

Syntheses and conformational properties. It was envisioned that the chiral three-blade propeller-shaped hextuple helicene D_3 -**2** of formula $C_{90}H_{48}$ could be prepared by a Yamamoto-type cyclotrimerization of 9,10-dibromo[7]helicene **1** (Figure 1a). This

new chiral PAH embeds three homochiral [7]helicene units on its outer shell and three homochiral [5]helicene units of opposite configuration on its inner edges. [7]Helicene itself has a high barrier to enantiomerization ($178.8 \text{ kJ}\cdot\text{mol}^{-1}$)^[9] precluding its inversion of configuration at a significant rate under the projected reaction conditions (ca. 130 °C). It was assumed that the barriers to inversion of configuration of the various [7]helicene-containing species involved in the planned nickel(0)-mediated cyclotrimerization would be too high for the synthesis to rely on a thermodynamic control as in previous studies.^[7,8] Thus, it should

be possible to perform the synthesis from enantiopure (P) - or $(M)-1$ to obtain the corresponding enantiopure hextuple helicene D_3-2 in an enantiospecific manner. Indeed, the nickel(0)-mediated cyclotrimerization of $(M)-1$ afforded $(-)-(M,M,M,P,P,P)-D_3-2$ in a 38% yield (Figure 1a). The same reaction performed with $(P)-1$ gave $(+)-(P,P,P,M,M,M)-D_3-2$ in a 39% yield (not depicted). Both enantiomers of D_3-2 were thus directly obtained as enantiopure hextuple helicenes, as confirmed by analytical chromatography on a chiral stationary phase. The structure and absolute configuration of $(-)-(M,M,M,P,P,P)-D_3-2$ were unambiguously

confirmed by single-crystal X-ray diffraction methods (Figure 1b) and circular dichroism spectroscopies (see Supporting Information). On a stereochemical point of view, ten diastereomers of **2** are possible: two of C_1 symmetry, six of C_2 symmetry and two of D_3 symmetry. Their relative free Gibbs energies were calculated by DFT methods from 0.0 kJ·mol⁻¹ for D_3 -**2**, the thermodynamic diastereomer, up to 108.3 kJ·mol⁻¹ for a C_2 -symmetric metastable diastereomer. A plausible enantiomerization pathway for D_3 -**2** was computed with a barrier to enantiomerization calculated at 160.6 kJ·mol⁻¹ (Figure 1c), in agreement with a value experimentally determined at 162.0 kJ·mol⁻¹ corresponding to a racemization half-life $t_{1/2}$ = 43 million years at 25 °C or 1.3 years at 130 °C. Notably, the barrier to enantiomerization of D_3 -**2** is lower than for the parent [7]helicene, an oddity for D_n symmetric multi-helicenes in general.^[5] Amusingly, hexuple helicene D_3 -**2** is the second triskelion-shaped nanographene reported within a short period of time.^[4e] The enantiospecific synthesis of both enantiomers of D_3 -**2** from either (*P*)- and (*M*)-**1** confirmed our hypothesis that no significant inversion of configuration of [7]helicene units can occur at a significant rate in the various synthetic intermediates involved in its synthesis. This translated in a unique opportunity to synthesize diastereoselectively a diastereomer of D_3 -**2** from racemic **1**, this time mixing helicities of the [7]helicene units at the outer shell of the molecule. Accordingly, the nickel(0)-mediated cyclotrimerization of rac-**1** allowed the formation of both the racemic (*P,M,P,P,P,M*)- C_2 -**2** and D_3 -**2** diastereomers in a 13.8:1 ratio and the isolation of (*P,M,P,P,P,M*)- C_2 -**2** in a 16% yield (Figure 1d); note that hexuple helicene rac-(*P,M,P,P,P,M*)- C_2 -**2** can also be denominated rac-(*P,P,M,M,P,P*)- C_2 -**2** or rac-(*M,P,P,P,M,P*)- C_2 -**2** according to the proposed nomenclature. The structure and relative configurations of rac- C_2 -**2** were ascertained by single-crystal X-ray diffraction analysis (Figure 1e). The free Gibbs energy of diastereomer C_2 -**2** was calculated at +32.2 kJ·mol⁻¹ relative to D_3 -**2**, and diastereomer C_2 -**2** is an intermediate in the computed enantiomerization pathway for D_3 -**2** (Figure 1c). The enantiomers of diastereomer C_2 -**2** were separated by chiral HPLC techniques and were fully characterized by chiroptical methods, including the attribution of their absolute configurations (see the Supporting Information).

Structural and chiroptical studies. The structural features of hexuple helicenes D_3 -**2** and C_2 -**2** were carefully examined (Figure 2). The four benzene units from the triphenylene core of D_3 -**2** show a marked alternation of bond lengths from 1.404 Å to 1.465 Å (mean values because of the crystallographic C_2 -symmetry of D_3 -**2**), to be compared to 1.393 Å in benzene, 1.420 Å in graphene, and 1.338 Å and 1.454 Å in 1,3-butadiene,^[10a,b] and may be regarded as their Kekulé structures, i.e. 1,3,5-cyclohexatrienes. The central ring in D_3 -**2** exists in a chair conformation and the three surrounding rings adopt severely twisted conformations with a mean torsion angle of 32.4° (Figure 2a). Evaluation of the photophysical properties of D_3 -**2** indicated a maximal absorption at 417 nm (ϵ = 90000 M⁻¹cm⁻¹) and maximal emission at 538 nm (quantum yield = 5.7%). The optical rotation

of (*M,M,M,P,P,P*)- D_3 -**2** was measured at $[\alpha]_D^{25}$ = -300 (c = 0.0325, CHCl₃), which is an unexpectedly small absolute value when compared to the large optical rotation values of isolated (*P*)-[5]helicene ($[\alpha]_D^{25}$ = +1670) and (*M*)-[7]helicene ($[\alpha]_D^{25}$ = -5900). Similarly, the electronic and vibrational circular dichroism spectra of D_3 -**2** were found of low intensity (see the Supporting Information). It was reasoned that the strong contribution to the chiroptical properties of the three moderately stretched homochiral (*M*)-[7]helicene units at the outer shell in (*M,M,M,P,P,P*)- D_3 -**2** (mean interplanar angle of the two terminal rings = 39.7° vs 32.3° in [7]helicene itself^[11a,b]) is somehow compensated by a strong contribution of opposite intensity of the three severely stretched homochiral (*P*)-[5]helicene units at its edges (mean interplanar angle of the two terminal rings = 64.0°

Figure 2. Some structural features of D_3 -**2** and C_2 -**2**. (a) The triphenylene core in D_3 -**2** including remarkable torsion angles and bond lengths (mean values). The solid-state conformation of D_3 -**2** has crystallographic C_2 -symmetry, justifying for the non-equivalent torsions in all the three blue-colored rings. (b) The triphenylene core in C_2 -**2** including remarkable torsion angles and bond length. The solid-state conformation of C_2 -**2** has no crystallographic symmetry, justifying for the non-equivalent torsions in the two white-colored rings. (c) The naphthalene unit along the molecular C_2 axis in C_2 -**2** showing a very high end-to-end torsion. (d) Profile view of the most twisted benzene ring in C_2 -**2**.

vs 46.0° in [5]helicene itself^[11c]). The structural analysis of C_2 -**2** also revealed a pronounced bond lengths alternation of the four benzene units from its triphenylene core, with bond lengths

generally comparable with those in *D*₃-**2**. However, the longest interatomic distance in *C*₂-**2** is the C–C bond crossed by the *C*₂ axis in the periphery of the triphenylene core has a length of 1.474 Å (Figure 2b), comparable with the one of the C(sp²)–C(sp²) single bond in some biphenyls.^[10c] The *C*₂-**2** diastereomer was found significantly more distorted than isomer *D*₃-**2**, with a maximal torsion angle culminating at 36.9° (!) for the peripheral ring of the triphenylene core on the *C*₂ axis, establishing the current record of torsion for a “benzene” ring (Figures 2b,d). Also, the naphthalene unit aligned with the *C*₂ axis in *C*₂-**2** exhibits a very high end-to-end torsion of 66.7° (Figure 2c, current record = 69.5°^[6]). The optical rotation of (*P,M,P,P,P,M*)-*C*₂-**2** was measured at [α]_D²⁵ = +705 (c = 0.0337, CH₂Cl₂) and its electronic circular dichroism spectrum showed a relatively low intensity (see Supporting Information), chiroptical features comparable with those of diastereomer *D*₃-**2**. The highly distorted structures of *D*₃-**2** and *C*₂-**2** limit the formation of intermolecular π–π interactions, thus allowing enhanced solubility in organic solvents. This is well illustrated by the crystal packing of (*M,M,M,P,P,P*)-*D*₃-**2** that shows few interactions between the individual molecules that stack to form supra-helices of (*P*) configuration within the crystal, creating large chiral CDCl₃ solvent channels organized along the a and b crystallographic axes (Figure 3).

Figure 3. (a) Crystal packing of (*M,M,M,P,P,P*)-*D*₃-**2** and representation of the solvent channels along the b axis. The content of the channels is a mix of explicitly determined *d*1-chloroform molecules and the calculated mask of solvent (yellow voids). (b) Representation of the (*P*)-configured supra-helix (pitch = crystallographic c vector = 27.2785 Å) in the crystal packing of (*M,M,M,P,P,P*)-*D*₃-**2**: side view along the c axis, the four-fold 4₃ screw axis is in red, the centroids of the central rings of each molecule are represented as red dots and the distances between them (Å) are noted in green.

Evaluation of aromaticity. The hextuple helicenes *D*₃-**2** and *C*₂-**2** sustain unprecedented distortion for stable PAHs, pointing out for unusual deficiencies in local aromaticity. Aromaticity is an extremely useful and popular concept in chemistry although there is no single quantitative definition of it, and it is not directly measurable experimentally.^[12] Application of the qualitative Clar's rule^[13] to *D*₃-**2** (or *C*₂-**2**, stereochemistry is not accounted for in Clar's structures) predicts an alternation of local aromaticity with 13 separated π-sextets in the Clar's structure containing the largest number of disjoint aromatic π-sextets (Figure 4d), and nine

disjoint π-sextets in the complementary Clar's structure. However, the Clar's rule is strictly valid for planar polycyclic aromatic systems. Structural-^[14] energetic-^[15] electron density-based,^[16] and magnetic-based indices^[17] have been developed to characterize and to quantify aromaticity as a property of molecules. However, these indices were also developed for planar systems and their transposition to three-dimensional systems can lead to erratic results. For instance, it was earlier recognized that the popular structural-based indices as HOMA (Harmonic Oscillator Model of Aromaticity) and energetic-based indices as TRE (Topological Resonance Energy), as well as some electron density-based methods, do not perform well for coiled systems as [*n*]helicenes and can lead to discrepancies.^[18] Indeed, we experienced difficulties with the HOMA during our early work (see Supporting Information). Actually, only magnetic-based methods appear applicable to severely twisted aromatics. When an external magnetic field is applied to a molecule, strong induced electrons currents are created at aromatic (diatropic currents) and antiaromatic (paratropic currents) rings. The ACID (Anisotropy of the Induced Current Density) method^[19] allows the visualization of an isosurface on which the induced current density vectors are plotted, showing diatropic (clockwise, aromatic) and paratropic (counterclockwise, antiaromatic) currents. However, the method is sensitive to the orientation of the applied external magnetic field, normally perpendicular to the molecular plane, which can be problematic with highly distorted PAHs such as *D*₃-**2** and *C*₂-**2**. The NICS (Nucleus Independent Chemical Shifts) index relies on the computation of the local magnetic environment at any desired point in space, often referred to as a ghost atom, and is expressed in ppm.^[20] NICS(0) values refer to ghost atoms placed at the center of each cycle, with large negative NICS(0) probing induced diatropic ring currents attributed to aromaticity. For instance, benzene has a NICS(0) calculated at -8.6 ppm at the level of theory employed herein. Although the combination of both methods allows for a qualitative and quantitative description of the induced electron currents, it should be kept in mind that the connection between induced diatropic ring currents and aromaticity is not straightforward.^[12b,17]

The NICS analysis of *D*₃-**2** (Figure 4a) allowed identifying three groups of rings with distinct local aromaticity: i) the A and B rings of the triphenylene core have NICS(0) values comprised between -0.6 and +0.8 ppm accounting for poorly directional induced ring currents indicating a non-aromatic character of these two rings; ii) the C and D rings have deficient induced diatropic ring currents with NICS(0) values calculated around -5.3 ppm pointing out for marked deficient local aromaticity; and iii) the terminal E rings with NICS(0) values of -9.6 ppm denoting full aromaticity. The over-estimation of NICS in the terminal rings of [7]helicene is documented and is due to the magnetic coupling with the neighboring ring placed below or above.^[17a] Notably, for each [5]helicene and [7]helicene subunit in *D*₃-**2** an overall lower aromaticity than for the parent isolated [5]helicene and [7]helicene was computed (see graphs in Figure 4a). Also, the distribution of local aromaticity in the [7]helicene units in *D*₃-**2** differs significantly from the one of isolated [7]helicene with the central ring B being non-aromatic in *D*₃-**2**. In order to differentiate torsional effects

Figure 4. Aromaticity analysis in D_3-2 and C_2-2 . (a) NICS(0) values for all non-equivalent rings in D_3-2 . The graphs show the NICS(0) values for the [7]helicene and [5]helicene units in D_3-2 (solid red and blue lines, respectively) and isolated [7]helicene and [5]helicene (dashed lines). (b) NICS(0) values for all non-equivalent rings in C_2-2 . The graphs show the NICS(0) values for the [7]helicene and [5]helicene units in C_2-2 (solid red and blue lines, respectively) and isolated [7]helicene and [5]helicene (dashed lines). (c) ACID plot of D_3-2 , the magnetic field is applied along the +z axis perpendicular to the view plane pointing to the observer, diatropic currents are highlighted with blue and green arrows and paratropic currents are highlighted with red arrows. (d) Clar's perspective of D_3-2 showing 13 separated π -sextets; the Clar's perspective of C_2-2 would be identical. (e) ACID plot of C_2-2 , the magnetic field is applied along the +z axis perpendicular to the view plane pointing to the observer, diatropic currents are highlighted with blue arrows and paratropic currents are highlighted with red arrows.

from through-space and conjugation effects in the NICS(0) calculations of the triphenylene cores of both D_3-2 and C_2-2 , the NICS(0) were also computed for the virtual triphenylene molecules having the distorted geometries D_3-2 and C_2-2 (see the Supporting Information). Comparison with the NICS(0) of triphenylene itself showed an augmentation of ca. +2 ppm for the distorted rings when compared to their planar counterparts, showing that torsional effects have a significant contribution to the unusual NICS(0) value computed for D_3-2 and C_2-2 . The ACID plot of D_3-2 (Figure 4c) confirmed the NICS analysis: the external E rings display clear and strong diatropic ring currents consistent with full aromaticity, the C and D rings exhibit dominant diatropic ring currents but of lower intensity, while the A and B rings show competing small diatropic and paratropic currents indicating weak electronic delocalization and a non-aromatic character. The triphenylene core in D_3-2 is probably the least aromatic known triphenylene unit, which correlates with its unprecedented torsion. More globally, a strong diatropic macrocyclic ring current is clearly visible at the periphery of the whole molecular architecture showing global electronic delocalization, which is certainly compensating for the severe distortions of the π -systems and contributing to the thermodynamic stability. The analysis of local

aromaticity in diastereomer C_2-2 revealed comparable features to the one of D_3-2 with however a more complex situation due to the lower symmetry of the molecule (Figures 4b,e). Notably, the two homochiral [7]helicene units (those not crossed by the C_2 axis) and the triphenylene core have different NICS(0) values. The ACID plot of C_2-2 confirmed qualitatively its overall distribution of local aromaticity. Altogether, the multi-helicenes D_3-2 and C_2-2 are PAHs whose local aromaticity is subjected to variations of large amplitudes from entirely aromatic at the edges to non-aromatic at the cores, correlating the distribution of distortion in the molecules.

Complexation properties of multi-helicene D_3-2 .

[7]Helicene itself was earlier demonstrated to behave as a chiral molecular tweezer for silver(I) ions, the metallic cation being sandwiched between the two outermost bonds of the helicene (C3–C4).^[21] It was hypothesized that hexuple helicene D_3-2 embedding three identical and moderately stretched [7]helicene units on its outer shell could behave as a mono, bis or triple tweezer capable of complexing up to three silver(I) ions to form some original chiral cationic metal-nanographene hybrids (Figure 5). The binding energies for the iterative complexation of one, two

and three silver(I) ions inside the bay region of three [7]helicene units in D_3 -**2** were evaluated by DFT calculations and compared to the one of Ag^+ with [7]helicene^[21] (see the Supporting Information). This model study indicated a slightly better

Figure 5. Computationally optimized structures of the most stable mono, bis and triscationic Ag^+ complexes of D_3 -**2** (DFT, wB97XD/Def2TZVP//wB97XD/Def2SVP, gas phase). Left : $[\text{Ag}\subset D_3\text{-2}]^+$, middle : $[2\text{Ag}\subset D_3\text{-2}]^{2+}$, right : $[3\text{Ag}\subset D_3\text{-2}]^{3+}$.

stabilization for $[\text{Ag}\subset D_3\text{-2}]^+$ than for $[\text{Ag}\subset [7]\text{helicene}]^+$, and also that triscation $[3\text{Ag}\subset D_3\text{-2}]^{3+}$ should be reasonably stable. Experimentally, a methanol/dichloromethane solution of D_3 -**2** and AgNO_3 (1:1) was analyzed by electrospray ionization mass spectrometry (ESI-MS) using very soft conditions, drastically limiting the generation of ions upon collision in the interface of the mass spectrometer (*i.e.* in the gas phase), so that most, if not all, observables result from the electrospray of cationic species initially present in solution. The formation of both the cation $[\text{Ag}\subset D_3\text{-2}]^+$ and the biscation $[2\text{Ag}\subset D_3\text{-2}]^{2+}$ in the solution could be clearly evidenced. However, performing ion mobility separation (IMS) prior to mass analysis to further enhance the dynamic range of detection permitted to evidence that $[3\text{Ag}\subset D_3\text{-2}]^{3+}$ is also a stable complex. The relative stability of the three silver adducts was evaluated by the 11.2:100:3.8 abundance ratio measured for $[\text{Ag}\subset D_3\text{-2}]^+ / [2\text{Ag}\subset D_3\text{-2}]^{2+} / [3\text{Ag}\subset D_3\text{-2}]^{3+}$ by IMS-MS, clearly showing the biscationic $[2\text{Ag}\subset D_3\text{-2}]^{2+}$ complex as the most stable one when observed as naked gas phase ions. The actual reasons for this preference remain unclear at this stage and may include the existence of a more compact and better adjusted conformation for biscationic $[2\text{Ag}\subset D_3\text{-2}]^{2+}$ than for its mono- and triscationic analogues as seemingly indicated by the experimental determination of collision cross sections (see Supporting Information).

Conclusions

The molecular design and concept using π -system elongation and steric effects, based on helical strains surrounding a triphenylene core with configurationally stable [7]helicenes, has led to extreme distortion in some chiral PAHs. This idea was put into practice through a nickel(0)-mediated cyclotrimerization of enantiopure and racemic 9,10-dibromo[7]helicene, which diastereoselectively afforded large chiral hextuple helicenes of formula $\text{C}_{90}\text{H}_{48}$ with D_3 and C_2 symmetry, respectively. The diastereomer with D_3 symmetry is a three-blade propeller-shaped chiral nanographene that embeds three homochiral [7]helicene units on its outer shell and three homochiral [5]helicene units of opposite configuration on its inner edges. Both D_3 -symmetric enantiomers were directly obtained as enantiopure materials by an enantiospecific Yamamoto-type cyclotrimerization, a premiere for large chiral

PAHs, and a first example for this type of cyclotrimerization. The structural analysis of this molecule revealed a highly distorted triphenylene core with a marked bond lengths alternation of the six-membered rings. The diastereomer with C_2 -symmetry embeds three [7]helicene units of mixed helicity on its outer shell, and three [5]helicene units of mixed helicity on its inner edges so that four (*P*)-configured and two (*M*)-configured helicenes are present in the molecule. Its structural analysis also enlightened a pronounced alternation of bond lengths in its triphenylene core, and more remarkably extreme torsions establishing new limits for benzene (twist = 36.9°). The chiroptical properties of the two hextuple helicenes were found of relatively small magnitude, possibly due to a phenomenon of compensation between the intertwined (*P*)- and (*M*)-configured helicenes. Aromaticity was computationally analyzed in these fascinating molecules using several methods, which was complicated not only because the quantification of the concept of aromaticity is intrinsically difficult, but also because existing models of aromaticity were developed for planar PAHs. Nevertheless, magnetic-based methods known as NICS and ACID proved to be useful, though not ideal, and they revealed a non-aromatic character of the triphenylene cores in both diastereomeric hextuple helicenes, in correlation to the severe distortion of the rings. An early exploration of the metal ions avidity and supramolecular properties of the D_3 -symmetric diastereomer revealed its ability to bind up to three silver(I) ions in the bay regions (cavities) of three [7]helicene units at its outer shell, as evaluated by the combination of DFT simulations with advanced mass spectrometry methods, opening the door to the field of chiral cationic metal-nanographene hybrids. To sum it up, the present study pushes the limits on the design and the synthesis of highly distorted chiral PAHs, where chirality provides additional control on molecules for modulating their properties for applications in chemical and materials science. It also deepens the knowledge on the conformational, chiroptical and supramolecular properties (solid and solution states) of chiral PAHs and nanographenes, and raises questions about aromaticity in these large distorted molecules.

Experimental Section

Detailed experimental procedures for the syntheses of (–)- D_3 -**2**, (+)- D_3 -**2** and rac- C_2 -**2**, the resolution of rac- C_2 -**2** by HPLC methods, the spectroscopic, structural, chiroptical, and photophysical characterization of all compounds, the experimental and computational enantiomerization study of D_3 -**2**, the full-detail analysis of aromaticity in D_3 -**2**, C_2 -**2** and related molecules, the full-detail complexation study of silver(I) cations with D_3 -**2**, and the crystallographic data for (–)-(*M,M,M,P,P,P*)- D_3 -**2** (CCDC 1835903) and rac-(*P,M,P,P,P,M*)- C_2 -**2** (CCDC 1902495) are included as supporting information for this article.

Acknowledgements

We thank Mrs. R. Rosas (Aix-Marseille Univ.) and Mrs. C. Troufflard (Sorbonne Univ.) for assistance with NMR spectroscopy, Prof. Dr. P. Ceroni (Univ. of Bologna) for assistance with photophysics, Mrs. M. Jean (CNRS) for assistance with HPLC, and the Centre Régional de Compétences

en Modélisation Moléculaire (Aix-Marseille Univ.) for computing facilities. Financial support from a CNRS PICS (No.PICS07573) with the University of Bologna, the French-Italian University for a doctoral contract to M.V. (No C2-141 - Vinci program), AMIDEX (Pyrenex, A-M-AAP-EI-17-171-170301-11.50-GINGRAS-SAT), Aix-Marseille Université and the Centre National de la Recherche Scientifique (CNRS) is gratefully acknowledged.
