MRI, Contrast agent, Manganese ions, Pyclen

Abstract

Magnetic resonance imaging (MRI) has a leading place in medicine as an imaging tool of high resolution for anatomical studies and diagnosis of diseases, in particular for soft tissues that cannot be accessible by other modalities. Many researches are thus focused on improving the images obtained with MRI. This technique has indeed poor sensitivity, which can be compensated by using a contrast agent (CA). Today, the clinically approved CAs on market are solely based on gadolinium complexes that may induce nephrogenic systemic fibrosis (NSF) for patients with kidneys failure, while more recent studies on healthy rats also showed Gd-retention in the brain. Consequently, researchers try to elaborate other types of safer MRI CA like manganese-based complexes.

In this context, the synthesis of the Mn^{2+} complexes of four 12-membered pyridine-containing macrocyclic ligands based on the pyclen core was accomplished and described herein. Then, the properties of these Mn(II) complexes were studied by two relaxometric methods, ^{17}O NMR spectroscopy and ^1H NMR dispersion profiles. The time of residence (τ_{M}) and the number of water molecules (q) present in the inner-sphere of coordination were determined by these two experiments. The efficacy of the pyclen-based Mn(II) complexes as MRI CAs was evaluated by proton relaxometry at a magnetic field intensity of 1.41 T near those of most medical MRI scanners (1.5 T). Both the ^{17}O NMR and the NMRD profiles indicated that the four hexadentate ligands prepared herein left one vacant coordination site to accommodate one water molecule

rapidly exchanging, in around 6 ns. Furthermore, it has been shown that the presence of an additional amide bond formed when the paramagnetic complex is conjugated to a molecule of interest does not alter the inner-sphere of coordination of Mn which remains monohydrated. These complexes exhibit r_1 relaxivities large enough to be used as clinical MRI CAs (1.7–3.4 mM⁻¹·s⁻¹, at 1.41 T and 37°C).

Introduction

Gadolinium complexes are currently the main contrast agents (CAs) authorized and used in the clinics for medical diagnosis by Magnetic Resonance Imaging (MRI). In fact, this powerful non-invasive imaging technique often requires the use of a CA to compensate its lack of sensitivity. Different classes of CAs have been developed for MRI, yet gadolinium complexes are by far the most used in the clinical field thanks to their property to decrease the water longitudinal relaxation time of protons, highlighting on the images the areas where the CA is accumulated.¹ Nevertheless, some researches have demonstrated since more than a decade that the injection of gadolinium complexes to patients with kidneys failure can trigger apparition of a disease called nephrogenic systemic fibrosis (NSF).^{2–5} This is particularly true for linear gadolinium complexes based on acyclic ligands such as Gd-DTPA (diethylenetriamine penta acetic acid gadolinium complex) that are less thermodynamically and kinetically stable than those based on macrocyclic complexes such as Gd-DOTA (1,4,7,10-tetraazacyclododecane-1,4,7,10-tetraacetic acid gadolinium complex). Therefore, some marketed Gd-based CAs (GBCAs) are no longer recommended for these patients.^{2,3,6} In addition, more recent studies have shown accumulation in the brain of gadolinium CAs in subjects with normal renal function.^{7,8} Further investigations were carried out on rats to compare macrocyclic (Gadoteridol[®]) with linear (Gadodiamide[®]) marketed agents and to quantify the Gd-species retained in the brain. It was concluded that

Gadoteridol[®] was much less retained than Gadodiamide[®] and fully detected in the urines as its intact and soluble Gd-species, whereas Gadodiamide[®] was found mostly as insoluble species.^{9,10} This situation explains that scientists are much interested in finding a safer next generation of MRI CAs based on Gd-free alternatives, and one of them could be the use of manganese-based CAs.^{11,12} Manganese ions are essential and naturally present in the body under the high-spin form of Mn²⁺ or Mn³⁺ with 5 or 4 unpaired d-orbital electrons, respectively. The normal physiological concentration of manganese in the serum of healthy subjects is about 0.05–0.12 µg/dL (9–22 µM)¹³, and part of its important biological role in the organism is to act as a cofactor activating certain enzymes or as a constituent in metalloenzymes. Manganese ions also play a role in the development of the immune and nerve systems function and in the regulation of the amount of vitamins and sugar in the blood.^{13,14} The first use of manganese as MRI CA was an oral formulation containing liposome-encapsulated MnCl₂ salt (LumenHance[®]) indicated for gastrointestinal examinations. However, several studies have shown that too high doses of free manganese ions could induce a neurodegenerative disorder called manganism, a disease with symptoms similar to those of the Parkinson's disease. Despite toxicity of free Mn²⁺ ions, manganese enhanced MRI (MEMRI) using MnCl₂ is used for preclinical studies in mice for brain¹⁵ or lung¹⁶ model tumors. To avoid adverse effects, manganese complexes have been developed, and the second manganese-based CA approved by the Food and Drug Administration (FDA) in 1997 was manganese dipyridoxyl diphosphate (Mn-DPDP, Teslascan[®], Figure 1) for use as a liver specific hepatobiliary CA.¹⁷ This structure is based on a linear ligand and has low thermodynamic and kinetic stabilities with consequently a certain amount of free manganese ions released *in vivo*. The efficacy of the Mn-DPDP as a MRI CA is quite low because the ligand does not allow a coordination bond with one water molecule in the

inner-sphere of metal coordination. The interest of such a candidate as CA comes therefore from the part of the released manganese ions whose relaxivity is $2.8 \text{ s}^{-1}\cdot\text{mM}^{-1}$ at 20 MHz and 40°C in aqueous solution; as a point of comparison, the relaxivity of Gd-DOTA which is a well-known commercialized macrocyclic CA is $3.5 \text{ s}^{-1}\cdot\text{mM}^{-1}$ at 20 MHz and $3.1 \text{ s}^{-1}\cdot\text{mM}^{-1}$ at 60 MHz and 37°C .^{18,19} As a result and for safety concerns (potential toxicity of released free Mn^{2+}), Mn-DPDP is no longer commercialized for clinical use, so there is still need for Gd-free alternatives, with higher thermodynamic stability and kinetic inertness in order to avoid the release of free manganese ions *in vivo*, and with a higher efficacy to be competitive with GBCAs.^{4,5,11,19} As a possibility, researchers examined if Mn-porphyrins, where the manganese cation is the center of a heme ring, can be used as MRI CAs: they found very high longitudinal and transverse relaxivities, of 9.33 and $12.0 \text{ s}^{-1}\cdot\text{mM}^{-1}$ at 3T (20°C) respectively, thereby enabling MRI detection *in vivo* of Mn-labelled cells.^{20,21} Porphyrins exhibit multiple advantages such as being able to stabilize manganese in its higher oxidation states Mn(III) or even Mn(V), needing to add a reducing agent in the medium such as sodium dithionite ($\text{Na}_2\text{S}_2\text{O}_4$) to insure the Mn(II) state.²² However, their synthesis is delicate in the perspective of scale-up production for an envisioned clinical use. Moreover, such compounds are highly light-sensitive, which is why they are intensively studied in a context of therapeutic agents for photodynamic therapy. Slightly larger ring-shaped ligands called texaphyrins complexing Mn^{2+} were recently proposed as bimodal CAs (MRI and photoacoustic imaging).²³ On the other hand, purely inorganic Mn-based nanoparticles (NPs) like antiferromagnetic MnO or paramagnetic Mn-doped ferrocyanide NPs (Prussian blues) were also tested as potential CAs for MRI.²⁴

In view of this effort of the community to develop macrocyclic ligands with high affinity for Mn(II) and high efficiency as MRI CAs²⁵, this report explores the potential of four Mn(II)

complexes based on the pycLEN core (3,6,9,15-tetraazabicyclo[9.3.1]pentadeca-1(15),11,13-triene) and carrying an additional site for the conjugation to a molecule of interest, for instance a chemotoxic drug or a polymeric vector. PycLEN is an interesting 12-membered macrocyclic structure that incorporates a *N*-pyridyl donor that rigidifies and pre-organizes the ligand coordinating groups (in particular rendering the 4 nitrogen atoms coplanar), an attribute that can improve the kinetic inertness of the resulting complex. PycLEN ligands have been reported recently for coordination of luminescent lanthanide cations to develop optical probes for near-infrared imaging.²⁶ The pyridine subunit also provides enhanced degree of lipophilicity that can promote mixed renal and hepatobiliary clearances, another interesting attribute in the context of patients with reduced kidney function. The choice of pycLEN-based chelating agents was also guided by their availability as “tailor-made” synthetic chelators prepared according to a versatile and potentially up-scalable strategy practiced by us and others which consists in assembling two synthons previously “dressed” with all the final functionalities required: the donor groups to satisfy the electronic demand of the paramagnetic ion, and an additional function to allow its conjugation to a molecule of interest.^{27–31} Since Mn(II) complexes typically have coordination numbers of 6 or 7, ligands for Mn(II) cannot exceed hexadenticity to allow the exchange of at least one water co-ligand in its inner-sphere that is a crucial parameter to insure interesting relaxometric properties for MRI applications. Consequently, it was necessary to cleverly functionalize the pycLEN derivative in order to limit to 6 its coordination bonds with Mn²⁺ while providing a sufficiently high degree of coordination to preserve satisfying thermodynamic stability of the complex.

Figure 1. Structures of the ligands discussed in this work : (A) DPDP¹⁷, (B) PCMA and PCMP²⁹, (C) PCTA, PC3AM^H, PC3AM^{Gly}, and PC3AM^{Pip},³² and (D) PC2A, PC2A-EA, and PCTA³³

The pyclen ([12]PyN4) macrocyclic core is now recognized to form efficient chelators for the Mn²⁺ cation complexation, and some studies can be found on the interest of such pyridine-containing (PC) ligands (figure 1). Drahos *et al.* have studied the influence on the thermodynamic stability, the kinetic inertness, the redox potential, and the ¹H and ¹⁷O relaxation rates by modifying the nature of the coordinating group on one arm of the macrocycle. They found that the mono-functionalized pyclens PCMA and PCMP with an acetate or a methyl phosphonate pendant arm give ternary hexacoordinate Mn²⁺ complexes accommodated with one water co-ligand (Figure 1), both of them being rather stable.²⁹ With a similar purpose, Garda *et al.* studied the influence on the proton relaxometry, the thermodynamic stability and the kinetic inertness of the presence of a primary, a secondary or a tertiary amide instead of the carboxylate functions of the PCTA which is a well know pyclen derivative.³² However, the corresponding Mn(II)-complexes show quite low relaxivities, less than 2 s⁻¹·mM⁻¹ at 37°C and 20 MHz. In a

more recent study, Botar *et al.* have developed a pH-responsive CA, [Mn(PC2A-EA)] stable and inert, with a maximum relaxivity at acidic pH of $3.5 \text{ s}^{-1} \cdot \text{mM}^{-1}$ at 20 MHz and 37°C .³³ All these results show that much efforts is still to be done to try increasing the efficacy of Mn-complexes as MRI contrast agents (Figure 1).

In this work, it was decided to study a series of four N_4O_2 hexadentate cyclen chelators including three structures carrying an additional function grafted onto the pyridine ring to allow conjugation to a molecule of interest (Figure 2). The “naked” complex MnL_1H where $-\text{H}$ designates absence of substituent in *ortho* position of the pyridine ring will be used as a reference to evaluate the impact of this additional subunit on the relaxometric properties of the corresponding Mn-complexes. Our previous work showed indeed that the functionalization of the carboxylate moiety into an amide bond on the pyridine arm of Gd-PCTA leads to a loss of one water molecule in the inner-sphere, giving $q = 1$ instead of $q = 2$.³¹ The syntheses are reported herein, together with the full relaxometric characterization of the corresponding Mn-complexes in order to have a complete understanding of their efficiency as MRI CAs (Figure 2).

Figure 2. Structure of the four Mn-complexes synthesized and studied in this work MnL_1H : $\text{MnPy}(\text{COO}^-)_2\text{-H}$; MnL_2COO^- : $\text{MnPy}(\text{COO}^-)_2\text{-OCH}_2\text{COO}^-$; MnL_3CH : $\text{MnPy}(\text{COO}^-)_2\text{-OCH}_2\text{CONHCH}_2\text{CCH}$ and $\text{MnL}_4\text{NH}_3^+$: $\text{MnPy}(\text{COO}^-)_2\text{-OCH}_2\text{CONH}(\text{CH}_2)_2\text{NH}_3^+$.

Results and discussion

Synthesis of the pyclyen-based Mn^{2+} complexes

The synthetic route to triamine **5b** is similar to that we described previously for the analogous compound bearing three acetate arms (Scheme 1).³¹ The selectively *N,N''*-protected diethylenetriamine derivative **2** was reacted in tetrahydrofuran (THF) with slight excess of both benzyl chloroformate and diisopropylethylamine (DIPEA) to afford the fully protected compound **3** in 94% yield. The next two steps, grafting of the acetate arms onto the secondary sulfonamides followed by cleavage of the *o*-nitrobenzenesulfonyl (Nosyl) protecting groups, were carried out in one-pot in warmed acetonitrile. For each of the two steps, the total consumption of both the starting materials and the monofunctionalized intermediate (*i.e.* **3** and **4a** for the first step; **4b** and **5a** for the second one) was carefully monitored (TLC and/or mass spectroscopy) and led to synthon **5b** with a yield of 85%.

Scheme 1. Synthesis of (a) NaOH, Nos-Cl, diethylether, THF, r.t. overnight (b) Cbz-Cl, DIPEA, THF, r.t. 1h30 (c_i)BrCH₂CO₂tBu, K₂CO₃, CH₃CN, reflux 3-5h (c_{ii})PhSH, K₂CO₃, 60°C 2-4h

As previously described for PCTA derivatives, the pyclen macro-ring formation was achieved by reacting the triamine **5b** with a small excess of 2,6-dibromomethylpyridine **6a-b** under heterogeneous conditions in refluxing acetonitrile at moderate dilution (0.01M) with sodium carbonate as scavenger (Scheme 2).³¹ In such conditions, the corresponding macrocycles **7a-b** were isolated in 39 and 64% yields respectively.

Scheme 2. Synthesis of (d) Na₂CO₃, CH₃CN, reflux

The macrocyclic pyclen skeleton built, successive step-by-step deprotections were necessary in order to allow selective grafting of different molecules of interest on the additional pendant group attached on the pyridine moiety and on the macrocycle (Scheme 3-5).

The carboxybenzyl group of compound **7a-b** was smoothly removed by a pallado-catalyzed hydrogenolysis under an atmospheric pressure of H₂ at room temperature and afforded compound **8a-b** (Scheme 3). The reaction can be performed in MeOH and EtOH but using of MeOH for **8b** can lead to transesterification. However, obtaining a mixture (if partial) of both methyl and ethyl esters does not impact the next step of saponification. The controlled removal of the ethyl ester group of compound **8b** was then achieved by mild saponification with NaOH

and provided the corresponding carboxylate **9** in 67% yield. The *tert*-butyl ester functions of the prochelators **8a** and **9** were removed by treatment with trifluoroacetic acid and led to the cyclen-based chelating agents **10a-b** that were finally complexed to Mn(II) by reaction with an equimolar amount of manganese dichloride tetrahydrate at controlled pH (*ca* 5-6) to give the Mn²⁺ complexes **11a-b**.

Scheme 3. Synthesis of (e) Pd/C, EtOH or MeOH, H₂ atm, r.t. overnight (f) NaOH, EtOH, r.t. (g) and (h) CF₃CO₂H, CH₂Cl₂, r.t. overnight (i) MnCl₂·4H₂O, H₂O, pH 5-6, 40°C overnight. **11a** is compound (MnL₁H), **11b** is compound (MnL₂COO⁻).

Compound **9** has an additional carboxylic acid function on the pyridine subunit to allow subsequent conjugation to an amine function of different molecules of interest (Scheme 3). As previously shown by us for a bifunctional PCTA chelator prepared to complex Gd^{3+} ,³¹ the resulting amide bond can act as an additional donor group so that the overall denticity of the chelator is increased, and the coordination of water molecule as co-ligand in the inner-sphere of the paramagnetic center can be compromised which has a negative impact on the relaxivity of the chelate. Consequently, it was decided to study the impact of this additional amide bond on the relaxivity of the Mn^{2+} complexes.

Both compounds **14** and **17** were designed with a dual purpose: to study the influence of an additional pendant amide bond on relaxometry, and to vary the function to allow subsequent conjugation for forthcoming studies: by click chemistry with Huisgen's 1,3-cycloaddition on the alkyne end-group, or by coupling the primary amine with carboxylic acid groups (Schemes 4-5).

On the one hand, propargylamine was grafted to compound **9** using the uronium-based activating agent HBTU (*O*-(benzotriazol-1-yl)-*N,N,N',N'*-tetramethyluronium hexafluorophosphate) and afforded the carbamoyl derivative **12** (over 90 % yield) whose *tert*-butyl ester functions were then removed upon treatment with trifluoroacetic acid. The resulting pycnen-based chelating agent **13** as trifluoroacetic salt was finally complexed to Mn(II) as previously done for **10a-b** (Scheme 4).

Scheme 4. Synthesis of (j) HBTU, $\text{NH}_2\text{CH}_2\text{CCH}$, DIPEA, CH_2Cl_2 , r.t. 4h30 (k) TFA, CH_2Cl_2 , r.t. 1 day (l) $\text{MnCl}_2 \cdot 4\text{H}_2\text{O}$, H_2O , pH = 5-6, 40°C overnight. The final product is compound (MnL_3CH).

On the other hand, the ethyl ester derivative **7b** was submitted to aminolysis in ethylenediamine at room temperature for 1 hour and led to the expected amido derivative **15** in 58% yield. Compound **15** was then submitted to acidolyses with hydrogen bromide in warmed acetic acid to cleave both the *tert*-butyl ester and the carbamate functions and led to the expected ligand **16a** in 72% yield. It is noteworthy that upon treatment with hydrogen chloride in diethyl ether solution at room temperature, even repeatedly, only partial cleavage of the benzyloxycarbamate function was observed and gave a mixture of the desired compound **16a** and of the intermediate **16b** (as hydrochloride forms). Complexation with Mn^{2+} finally proceeded very easily, in few minutes at room temperature (Scheme 5).

Scheme 5. Synthesis of (m) $\text{NH}_2\text{CH}_2\text{CH}_2\text{NH}_2$, r.t. (n) HCl_{anh} , Et_2O or HBr_{anh} , AcOH , 70°C then r.t. (o) $\text{MnCl}_2 \cdot 4\text{H}_2\text{O}$, H_2O , pH 5-6, r.t.. The final product is compound $(\text{MnL}_4\text{NH}_3^+)$.

In order to ensure that manganese is in the oxidation state +2, the complexations were performed under argon atmosphere and a reducing agent, sodium dithionite (approximately 1.3 eq $\text{Na}_2\text{S}_2\text{O}_4$), was added to the solutions with the pH maintained between 7 and 8.²²

Relaxometric characterization

Determination of the number of coordinated water molecules

The determination of the number of water molecules in the inner coordination sphere (q) is very important to estimate the efficacy of the complexes as MRI contrast agents, as the longitudinal proton relaxivity r_1 is directly related to the number of coordinated water molecules, in permanent exchange with those of the solvent. Two different techniques were used to determine this q parameter for the Mn(II) complexes, developed respectively by E. Gale *et al.*

and J. Peters and C. Geraldes. The first technique is based on ^{17}O NMR spectroscopy where the water transverse relaxivity r_2 is measured as a function of temperature.³⁴ (Figure 3) The method is then based on the maximum ^{17}O transverse relaxivity, $r_{2\text{max}}^0$, measured in this case at low temperature (equation 1). This equation is obtained by different approximations, as explained by E. Gale *et al.*, and the $r_{2\text{max}}^0$ measured at 11.75 T lead to the results shown in Table 1. The number q is approximately the same for all complexes and close to one.³⁴ To confirm these results, a second technique was used, based on the measurement of NMRD profiles (*i.e.* the water proton longitudinal relaxivity r_1 as a function of magnetic field or proton resonance frequency) at 25°C, developed by J. Peters and C. Geraldes.³⁵ (Figure 4) This is based on another equation related to the proton longitudinal relaxivity at low field (on the plateau of the NMRD profile) and the formula weight (FW) of the complex (equation 2). The results (Table 1) confirm the presence of one coordinated water molecule in the inner sphere for the four synthesized complexes. The slight difference between the results coming from the two techniques can be explained by the fact that both methods rely on different approximations. The presence of one coordinated water molecules is an interesting result since it shows that the presence of the arm on the pyridine moiety, with or without amide bond, does not change the number of coordinated water molecules, meaning that this appended functionality does not participate to the coordination bounds with the manganese ion. It will thus allow further grafting of molecules of interest in a forthcoming study.

Figure 3. Measurements of the ^{17}O water transverse relaxivity versus inverse of temperature, at 11.75 T, in the presence of the different Mn-complexes at 2.06 mM (MnL_1H , triangles), 2.58 mM (MnL_2COO^- , stars), 2.05 mM (MnL_3CH , circles) and 1.21 mM ($\text{MnL}_4\text{NH}_3^+$, squares) concentration in order to determine the number of inner sphere water molecule (q) from Formula (1) derived in reference 34 as a function of the maximum value $r_{2\text{max}}^0$.

Figure 4. NMRD profiles at 25°C in order to determine the number of inner sphere water

molecule (q) from Formula (2) derived in reference 35 as a function of the plateau value (r_{1p}) at low frequency and the formula weight (FW) for the four complexes: MnL_1H (triangles), MnL_2COO^- (stars), MnL_3CH (circles) and $\text{MnL}_4\text{NH}_3^+$ (squares).

Table 1. Evaluation of the number of coordinated water molecules in the inner sphere for all complexes by two different techniques

	$r_{2\text{max}}^0$ ($\text{s}^{-1}\cdot\text{mM}^{-1}$) (67.8 MHz)	q (Eq. 1)	r_{1p} ($\text{s}^{-1}\cdot\text{mM}^{-1}$) (25°C and 0.02 MHz)	q (Eq. 2)
MnL_1H	419.2	0.82 ± 0.2	7.7	1.25 ± 0.4
MnL_2COO^-	458.4	0.90 ± 0.2	8.3	1.30 ± 0.4
MnL_3CH	473.4	0.93 ± 0.2	9.4	1.35 ± 0.4
$\text{MnL}_4\text{NH}_3^+$	478.6	0.94 ± 0.2	10.0	1.42 ± 0.4

Determination of the exchange rate of the coordinated water molecule

The technique which allows to determine the lifetime of the coordinated water molecule was developed by T. Swift and R. Connick.³⁶ It is based on the measurement of the ^{17}O transverse relaxation rate as a function of temperature, as for the determination of q for the Mn(II) complexes. (Figure 5). The results (Table 2) show that the coordinated water molecule is in a fast exchange regime for the four complexes studied since residence times τ_M of the order of 6 ns are obtained.

Figure 5. Measurement of the ^{17}O water transverse relaxation rate as a function of the inverse of temperature, at 11.75 T, on solutions of each complex at 2.06 mM (MnL_1H , triangles), 2.58 mM (MnL_2COO^- , stars), 2.05 mM (MnL_3CH , circles) and 1.21 mM ($\text{MnL}_4\text{NH}_3^+$, squares). The continuous lines represent fits by the theoretical model developed in reference 36, with the parameters displayed in Table 2.

Table 2. Determination of the residence time at 37°C and 11.75 T of the coordinated water molecule (τ_{M}), as well as the other parameters characterizing this exchange : A/\hbar , the hyperfine coupling constant between the oxygen nucleus of the bound water molecule and the Mn^{2+} ion; τ_{v} , the correlation time modulating the electronic relaxation of Mn^{2+} ; E_{v} , the activation energy related to τ_{v} ; B , related to the mean-square value of the zero-field splitting energy Δ ($B = 2.4\Delta^2$); and ΔH^\ddagger and ΔS^\ddagger the enthalpy and entropy of activation, respectively, of the water exchange process. The number of coordinated water molecules was set to $q = 1$.

	τ_M (ns)	ΔH^\ddagger (kJmol ⁻¹)	ΔS^\ddagger (Jmol ⁻¹ K ⁻¹)	A/\hbar (10 ⁶ rads ⁻¹)	B (10 ²⁰ s ⁻²)	τ_V^{298} (ps)	E_V (kJmol ⁻¹)
MnL ₁ H	6.5 ± 0.4	29.7 ± 0.1	7.4 ± 0.2	-39.9 ± 2.5	3.3 ± 0.1	1.4 ± 0.1	33.2 ± 3.1

Relaxometric measurements and NMRD profiles to assess the efficiency as MRI CA

As a reminder, the relaxivity is defined as the increase of the water proton relaxation rate induced by one mmol per liter of paramagnetic complexes. Longitudinal (r_1) relaxivities were measured at 37°C and respectively 0.47 T (20 MHz) and 1.41 T (60 MHz) (Table 3). They are lower than that of the commercially available gadolinium complexes (the data for Gd-DOTA are, for comparison, 3.5 s⁻¹·mM⁻¹ at 20 MHz and 3.1 s⁻¹·mM⁻¹ at 60 MHz and 37°C), as expected part due to the intrinsic lower number of unpaired electrons for manganese (5) compared to that for gadolinium (7). The relaxivities could however be increased by grafting of the complexes on macromolecular entities that would reduce the tumbling rate of the complex, which enhances the interaction time between the nuclear magnetic moments of the water protons and the orbital one of the paramagnetic complex during an echo time of the NMR radiofrequency field pulse sequence, and therefore the spin relaxation mechanism.¹⁹ This is envisaged as outlook of this work in a near future.

NMRD profiles were performed for the four cyclen-based manganese complexes in order to evaluate the efficacy of each complex according to the magnetic field or frequency used. The fitting of these profiles according to the theory of Solomon and Bloembergen allows extracting important parameters to understand this efficacy such as the rotational correlation time (τ_R) or

“tumbling time”, the electronic relaxation time at zero field (τ_{S0}) and the correlation time that modulates electronic relaxation (τ_V).^{37–39} Among the four complexes studied, MnL_1H , has a r_1 NMR dispersion profile below the other curves, especially at low field. This difference can be ascribed to the electronic properties of the complex which are slightly less favorable than for the other ones: τ_{S0} is indeed lower compared to the values of the three other complexes. This is again encouraging for the future studies where we plan to graft other molecules thanks to the arm present on the pyridine moiety. (Figure 6)

Figure 6. 1H NMRD profiles at $37^\circ C$ for Mn^{2+} -complexes, showing the longitudinal relaxivity at varying proton Larmor frequency (aka varying magnetic field). The straight lines show the theoretical fitting based on the theory of Bloembergen and Solomon.^{37–39}

Table 3. Results of the theoretical fitting of 1H NMRD profiles at $37^\circ C$ with Bloembergen and Solomon's theory using the MINUIT minimization software. Parameters, such as the distance of closest approach (d_{NMR}) and the water diffusion coefficient (D) governing the outer sphere mechanism, or the distance between the coordinated proton of the water molecule and the manganese ion (r) related to the inner sphere mechanism, can be set constant during the fitting

procedure thank to their prior determinations along the study of the manganese complex properties.^{37–39} The values of q and τ_M used were also predetermined thanks to their separate evaluation described above, thereby allowing to evaluate the rotational correlation time (τ_R), the electronic relaxation time to ground level at zero magnetic field (τ_{SO}) and the correlation time that modulates electronic orbital relaxation (τ_V) at 37°C.

	MnL ₁ H	MnL ₂ COO ⁻	MnL ₃ CH	MnL ₄ NH ₃ ⁺

Transmetalation evaluation

It is now well-established that the kinetic inertness of a complex is a more important parameter than its intrinsic thermodynamic stability for *in vivo* applications. In order to define the stability of the manganese complexes against the most important endogenous divalent metal cations present in body fluids (Zn²⁺, Cu²⁺, Ca²⁺, Mg²⁺), a transmetalation study was performed in the presence of Zn(II) as exchanging metal cation. The choice of Zn²⁺ as challenger to assess the *in*

in vivo transmetalation behavior of the Mn(II) complexes was governed by the following considerations:^{40,41} i) none of the four competitive endogenous cations is paramagnetic and therefore does not respond to NMR; ii) Zn^{2+} is the second most abundant transition metal in the human body (33 ppm) after Fe^{3+} (60 ppm); iii) for a given exogenous ligand, complexes of Zn^{2+} as well as Cu^{2+} have generally higher stability than the corresponding Mn^{2+} complex as ascribed to LFSE effect (ligand field stabilization energy), whereas alkaline earth ions Ca^{2+} and Mg^{2+} , although present at higher concentrations in blood plasma than Zn^{2+} , form generally less stable complexes with the exogenous ligands generally studied for Mn^{2+} due to their absence of d electronic orbitals; iv) the concentration of Zn^{2+} in blood is higher compared to that of Cu^{2+} (5 to 100 times higher).⁴² As previously described by us,^{41,43} the transmetalation rate was assessed by measuring the progress of the proton relaxivity at 37°C and 20 MHz. The method consists in using a solution of the Mn-complexes at concentration 2.5 mM in phosphate buffer in the presence of an equimolar amount of zinc chloride. The proton longitudinal relaxation time (T_1) is then measured in order to determine paramagnetic relaxation rate R_1^P as a function of time. Indeed, when the exchange between Mn^{2+} and Zn^{2+} takes place, a precipitate of manganese phosphate ($\text{Mn}_3(\text{PO}_4)_2$) is formed. This process leads to an increase of T_1 and thus a decrease of R_1^P compared to its initial value $R_1^P(t=0)$, as ascribed to a decrease of paramagnetic ion concentration in solution.

The results (Figure 7) are similar for all the Mn complexes studied and show, during the first day, a small fast yet transient increase of the ratio $R_1^P/R_1^P(t=0)$, which could be due to the presence of transient polynuclear species coordinated to both Mn^{2+} and Zn^{2+} . This step is followed by a decrease of about 50% of the relaxation rate due to the formation of the insoluble solid as explained previously. This decrease is however quite slow ($t_{1/2}$ half-life of approximately

1350 min) and we can notice that at the first measurement of the second day, the relaxation rate reached 80% of the initial value of relaxation rate. As a conclusion, even though this study highlights a lack of kinetic stability towards the transmetalation with zinc ions after a long time, we can be confident for the use of those complexes *in vivo* given their expected fast clearance from the organism. Further *in vitro* toxicity and *in vivo* pharmacokinetic studies will however be necessary in the future to definitively demonstrate the biosafety of these paramagnetic MRI CAs.

Figure 7. Evolution of the normalized paramagnetic longitudinal relaxation rate in order to evaluate the transmetalation kinetics between manganese and zinc ions for the four Mn^{2+} -complexes: MnL_1H (triangles), MnL_2COO^- (stars), MnL_3CH (circles) and $MnL_4NH_3^+$ (squares). Experiment was performed during 5 days in phosphate buffer at 20 MHz and 37°C. The concentration of Mn-complexes and of competing Zn(II) salt used is 2.5 mM, which is much higher than its normal physiological level ($\sim 10 \mu M$).⁴⁴

Phantom images

As a proof of concept of the use of these manganese-complexes as MRI CAs, phantom MRI images were recorded both at preclinical (9.4 T) and clinical magnetic field (1 T), for each manganese complex at a concentration of 0.5 mM and compared with Gd-DOTA at the same concentration and with water (Figure 8). As expected, the images are highlighted for the four Mn-complexes compared to water but their contrast is less enhanced than with Gd-DOTA. Among the Mn-complexes, we can also notice a smaller highlighting effect for MnL_1H , which can be related to its smaller relaxivity because of the absence of the arm on the pyridine structure (Table 3).

Figure 8. Phantom images recorded at approximately 37°C under two different magnetic fields (1 T and 9.4 T) of each Mn^{2+} -complex at a concentration of 0.5 mM compared with a commercial Gd-complex, Gd-DOTA, at the same concentration, and with pure water.

Table 3. Values of longitudinal relaxivity calculated from the water proton relaxation time T_1 measured at approximately 37°C under a field of 9.4T (400 MHz).

	MnL_1H	MnL_2COO^-	MnL_3CH	$\text{MnL}_4\text{NH}_3^+$	Gd-DOTA
r_1 ($\text{s}^{-1}\cdot\text{mM}^{-1}$) 9.4T, 37°C	2.8 ± 0.1	2.7 ± 0.1	3.1 ± 0.1	2.95 ± 0.1	3.2 ± 0.1

Conclusions and perspectives

Four novel pycen-based complexing agents were synthesized and the molecular structure of intermediated compounds after each step of the synthesis was characterized. The corresponding manganese complexes were prepared and fully characterized by NMR relaxometry methods to evaluate the parameters governing their properties and efficacy as paramagnetic MRI contrast agents. This characterization is important in order to evaluate if the complexes have an efficacy close to the commercial gadolinium complexes, and could potentially replace them on market, if they pass further evaluation of their bio-safety.

Although these Mn-based compounds have been shown to be slightly less effective than the marketed Gd-based compounds as ascribed to lower magnetic moment of the metal, the potential of these pycen-based chelating compounds remains high. Their relaxivity could indeed be improved by different ways. Firstly, it will be possible to play on the rotational correlation time of the complex by blocking them in a nanostructure either organic (e.g. micelle or vesicle) or inorganic (e.g. silica nanoparticle), while keeping sufficiently small hydrodynamic size and stealthness to allow rapid clearance when injected in systemic circulation (which is a prerequisite for CAs used in clinics). Moreover, the additional chemical functions on the pyridine moiety will allow conjugation to biologically relevant vectors such as peptides or antibodies in order to target specific pathologies. Finally, on the basis of reported results, further improved kinetic inertness of the Mn^{2+} -complexes might be obtained in future by replacing the two acetate complexing groups by non-ionizable groups such as amides; in this case, the positive charge on the resulting cationic Mn^{2+} complexes could be protective against acid-assisted dissociation, although grafting of neutral macromolecules might be necessary in that case to insure stealthness against

adsorption of blood plasma proteins. It will nevertheless be important to verify that the presence of those amide functions does not increase too much the residence time in the inner sphere of the coordinated water molecule. As a conclusion, these preliminary results show very encouraging properties of pycen derivatives for MRI contrast properties, although further study is necessary to demonstrate that they can replace gadolinium complexes in clinical diagnosis of diseases (cancers, strokes...) by MRI.

Experimental section

Materials

Chemical and physical measurements:

The NMR spectra (^1H , ^{13}C , COSY, DEPT) were recorded at 298K and reported in ppm. (Bruker® AVANCEII-500 at 500 MHz, Bruker® AVANCE NEO at 400 MHz or Bruker® AVANCE NEO at 600 MHz). The multiplicity of the peaks is defined as s (singlet), d (doublet), t (triplet) and m (multiplet). The reactions were monitored by mass spectrometry (Waters®, ZQ-2000) and all the compounds were characterized by mass spectrometry (Waters® ZQ-2000, Waters® QDa, Waters® Quattro Premier or Waters® QToFUs). The ESI-LRMS was performed on 3200 QTrap (AB Sciex). The pH was controlled by Mettler Toledo® fiveEasy pH/mV. The relaxometry and NMRD profiles measurements were performed on Bruker® MiniSpec at 20 and 60 MHz at 37°C and on a fast field cycling (FFC) relaxometer between 0.02 and 40 MHz (Spinmaster, Stelar®, Italy). ^{17}O NMR measurements were performed on a Bruker® AVANCEII-500 at 67.8 MHz. The MRI measurements were performed on 1T (Bruker® ICON) and 9.4T (Bruker® Biospec) with a Rapid Acquisition with Relaxation Enhancement sequence

(RARE) (TE = 12 ms, TR = 350 ms, resolution = 156 x 146 microns, RARE factor = 2, 2 or 4 averages, slice thickness = 1.25 mm).

Chemical material and methods:

The flash chromatography was performed on Biotage® flash chromatography using pre-packed cartridges. The collection is based on absorption at 254 and 270 nm by UV detection.

Methods

Synthesis of the lower part

2-Nitro[N(2{2[(2-nitrophenyl)sulfonylamino]ethylamino})-ethyl]benzenesulfonamide

compound 2: It is synthesized according to the protocol of Devreux *et al.*³¹

Benzyl N,N-bis(2-((2-nitrophenyl)sulfonylamino)ethyl)carbamate *compound 3*: DIPEA (7.7 mL, 44.2 mmol, 1.2 eq) is added to a solution of disulfonamido amine **2** (17.6 g, 37.1 mmol) in THF (100 mL), followed by benzyl chloroformate (6.3 mL, 44.1 mmol, 1.2 eq) in one portion. The reaction is stirred overnight during which insoluble matter appeared. The mixture is concentrated to dryness. The crude material is taken up in CH₂Cl₂ (100 mL), and is washed with water (4 x 30 mL). The organic layer is dried then concentrated to dryness to afford the desired

compound **2** as a brown oil (21.2 g, 34.8 mmol). Yield 94%. ¹H NMR (CDCl₃, 400 MHz) δ (ppm): conformed to reported data of Kim *et al.*⁴⁵

Di-*tert*-butyl 2,2'-((((benzyloxy)carbonyl)azanediyl)bis(ethane-2,1-diyl))bis

(azanediyl)diacetate *compound 5b*: A suspension of the previously prepared compound **3** (1.61 g, 2.65 mmol) with potassium carbonate (810 mg, 5.86 mmol, 2.2 eq) in acetonitrile (22 mL) is refluxed for 15 minutes. *tert*-Butyl bromoacetate (900 μL, 6.09 mmol, 2.3 eq) is added in one portion. The reaction is monitored by MS and/or TLC (Cyclohexane/AcOEt 1/1 v/v, UV detection). After 1.5h, total conversion of both the starting triamine **3**, and of the mono-*N*-alkylated intermediate **4a** is observed leading to the di-*N*-alkylated disulfonamide **4b**. The reaction mixture is cooled, and a second portion of potassium carbonate (1.60 g, 11.92 mmol, 4.4 eq) is added, followed by thiophenol (810 μL, 7.94 mmol, 3.0 eq) in one portion. The reaction is monitored by MS and/or TLC (Cyclohexane/AcOEt 1/1 v/v, UV detection: CH₂Cl₂/MeOH 97.5/2.5 v/v, UV and ninhydrin stain detection). After 2.5h, total conversion of the intermediate compounds **4b** and **5a** is obtained. The reaction mixture is allowed to cool to room temperature. Insoluble matter is filtered off through Celite[®], and the organic filtrate is concentrated to dryness. The resulting canary yellow colored oil is purified by chromatography on silica gel (CH₂Cl₂/MeOH 10/0 to 8/2 v/v) and led to the desired product **5b** as an orange oil (1.051 g, 2.26 mmol). Yield 85%. ¹H NMR (CDCl₃, 400 MHz) δ (ppm): 1.44 (s, 18H, -tBu); 2.73-2.90 (m, 4H, -N-CH₂-CH₂-N-); 3.22-3.36 (m, 4H, -CH₂-CO₂tBu); 3.44 (broad s, 4H, -N-CH₂-CH₂-N); 5.12 (s, 2H, -CH₂-Ph); 7.26-7.38 (m, 5H, CH_{Ar}). ¹³C NMR (CDCl₃, 100 MHz) δ (ppm): 28.1 (-tBu); 47.7, 48.0, 48.2, and 48.5 (-N-CH₂-CH₂-N); 51.2 (-CH₂-CO₂tBu); 67.3 (-

CH₂-Ph); 81.6 (C_{quat}tBu); 127.9, 128.0, and 128.6 (CH_{Ar}); 136.7 (C_{quat}Ph); 156.4 (-N-CO₂Ph); 171.0 (-CO₂tBu).

Synthesis of the upper parts

2,6-Bis(bromomethyl)pyridine *compound 6a*: It is synthesized according to the protocol of Dioury *et al.*²⁸

Ethyl ((2,6-bis(bromomethyl)pyridin-3-yl)oxy)acetate *compound 6b*: It is synthesized according to the protocol of Devreux *et al.*³¹

Synthesis of MnPy(COO⁻)₂-H (Compound MnL₁H)

Benzyl 3,9-bis(2-tert-butoxy-2-oxo-ethyl)-3,6,9,15-tetrazabicyclo[9.3.1] pentadeca-1(14),11(15),12-triene-6-carboxylate *compound 7a*: Solid Na₂CO₃ (480 mg, 4.53 mmol, 4 eq) is added to a solution of diamine lower part **5b** (530 mg, 1.14 mmol) with 2,6-bis(bromomethyl)pyridine **6a** (401 mg, 1.52 mmol, 1.3 eq) in acetonitrile (115 mL). The suspension is refluxed until completion of the reaction (MS and/or TLC monitoring; 1 hour). The insoluble matter is filtered off, and the filtrate is concentrated to dryness. The crude material obtained is purified by chromatography on silica gel (CH₂Cl₂/MeOH, 100/0 to 98/2 v/v). to give the desired compound **7a** as a thick oil (253 mg, 0.445 mmol). Yield 39%. ¹H NMR (CDCl₃, 400 MHz) δ (ppm): 1.43, and 1.44 (2 s[#], 18H, -tBu); 2.68-2.90 (m, 4H, -N-CH₂-CH₂-N-); 3.16-3.27 (broad t, *J* 7-7.80 Hz, 4H, -N-CH₂-CH₂-N-); 3.34, and 3.41 (2 broad s[#], 4H, -N-CH₂-); 3.91-

4.06 (m, 4H, -N-CH₂-); 5.01 (s, 2H, -CH₂-Ph); 7.13-7.31 (m, 7H, Ph, and -CH₂-C(N)-CH=CH); 7.61 (t, *J* 7.6 Hz, 1H, -CH₂-C(N)-CH=CH). #Double signal that may be due to rotamers (carbamate bond: free-rotation obstruction) ¹³C NMR (CDCl₃, 100 MHz) δ (ppm): 28.2 (-tBu); 44.9, and 45.3[§] (-N-CH₂-CH₂-N-); 51.6, and 52.1[§] (-N-CH₂-CH₂-N-); 59.0, and 59.2[§] (-N-CH₂-); 60.0, and 60.2[§] (-N-CH₂-); 66.8 (-CH₂-Ph); 81.2 (C_{quat}tBu); 122.9 (-CH₂-C(N)-CH=CH); 127.6, 127.8, 128.4 (3 CH_{Ar}Ph); 137.0 (C_{quat}Ph); 137.5 (-CH₂-C(N)-CH=CH); 156.1, 157.3, 157.7[&] (NCO₂, and 2 C_{quat}PyR); 170.6 (CO₂). [§]Although the symmetrical structure, each ¹³C appears to be diastereotopic; that may be due to rotamers from the carbamate bond (free-rotation obstruction). [&]Broad and small signal.

tert-Butyl 2-{9-[2-(tert-butoxy)-2-oxoethyl]-3,6,9,15-tetraazabicyclo[9.3.1] pentadeca-1(14),11(15),12-trien-3-yl}acetate *compound 8a*: Compound **7a** (240 mg, 0.42 mmol) is solubilized in EtOH following by the addition of Pd/C (24 mg). The solution is stirred 10 days under H₂ at atmospheric pressure. Insoluble material is filtered through Celite[®] and the filtrate is concentrated at relatively high temperature to eliminate the toluene which is the by-product to give the desired compound **8a**. The crude product is directly engaged in the next synthesis step. ¹H NMR (CD₃OD, 500 MHz) δ (ppm) : 1.46 (s, 18H, -tBu); 2.64-3.01 (broad s, 4H, -N-CH₂-CH₂-N-); 3.31 (broad t, *J* 5.3 Hz 4H, -N-CH₂-CH₂-N-); 3.51 (s, 2H, N-CH₂-N-); 3.99 (s, 4H, -CH₂-CO₂tBu); 7.01 (d, *J* 7.66 Hz, 1H, -CH=CH-CH=); 7.56 (t, *J* 7.65 Hz, 1H, -CH=CH-CH=).

2-[9-(Carboxymethyl)-3,6,9,15-tetraazabicyclo[9.3.1]pentadeca-1(14),11(15),12-trien-3-yl]acetic acid *compound 10a*: Compound **8a** (10 mg; 0.023 mmol) is solubilized in

dichloromethane (1 mL) and stirred following by the addition of trifluoroacetic acid (1 mL). Overnight, the solution is concentrated and washed two times with diethylether (4 mL) to give the desired compound **10a** (12 mg, 0.018mmol). Yield 79.8 % (determined by weighing). ^1H NMR (CD_3OD , 500 MHz) δ (ppm): 3.11 (broad t, J 5.21 Hz, 4H, -N- CH_2 - CH_2 -N-); 3.21 (broad t, J 5 Hz, 4H, -N- CH_2 - CH_2 -N-); 3.62 (s, 4H, -N- CH_2 -N-); 4.12 (s, 4H, - CH_2 - CO_2tBu); 7.25 (d, J 7.71 Hz, 2H, $\text{CH}=\text{CH}-\text{CH}=\text{}$); 7.79 (t, J 7.7 Hz, 1H, - $\text{CH}=\text{CH}-\text{CH}=\text{}$).

2-(12- $\{[(2\text{-aminoethyl})\text{carbamoyl}]\text{methoxy}\}$ -9-(carboxymethyl)-3,6,9,15-tetraazabicyclo[9.3.1]pentadeca-1(15),11,13-trien-3-yl)acetic acid manganese *compound 11a*: A solution of $\text{MnCl}_2 \cdot 4\text{H}_2\text{O}$ (7 mg, 0.035 mmol) in water (0.5 mL) is added dropwise to a solution of compound **10a** (12 mg, 0.018 mmol) in water (1 mL). The pH is adjusted and maintained to $5 < \text{pH} < 6$ with 0.1 M aqueous solution of NaOH. The mixture is warmed at 40°C overnight. The presence of free Mn^{2+} is revealed by the colorimetric test with orange xylenol. The aqueous mixture is treated with Chelex resin, then freeze-dried to give the desired compound **11a**. ESI-MS ($\text{C}_{15}\text{H}_{20}\text{MnN}_4\text{O}_4$): m/z 398.09 $[\text{M}+\text{Na}]^+$.

Synthesis of $\text{MnPy}(\text{COO}^-)_2\text{-OCH}_2\text{CO}_2^-$ (Compound MnL_2COO^-)

Benzyl 3,9-bis(2-tert-butoxy-2-oxo-ethyl)-12-(2-ethoxy-2-oxo-ethoxy)-3,6,9,15-tetraazabicyclo[9.3.1]pentadeca-1(14),11(15),12-triene-6-carboxylate *compound 7b*: Solid Na_2CO_3 (466 mg, 4.40 mmol, 4 eq) is added to a solution of triamine lower part **5b** (513 mg, 1.10 mmol) with dibromomethyl compound **6b** (444 mg, 1.21 mmol, 1.1 eq) in acetonitrile (110 mL). The suspension is refluxed until completion of the reaction (MS and/or TLC

monitoring; 1 hour). The insoluble matter is filtered off, and the filtrate is concentrated to dryness. The crude material obtained is purified by chromatography on silica gel (CH₂Cl₂/MeOH, 100/0 to 98/2 v/v) to give the desired compound **7b** as a thick oil (471 mg, 0.702 mmol). 2-(12-{{(2-Aminoethyl)carbamoyl}methoxy}-9-(carboxymethyl)-3,6,9,15-tetraazabicyclo[9.3.1]pentadeca-1(15),11,13-trien-3-yl)acetic acid *compound 16a.xHBr*: A concentrated solution of the fully protected precursor **15** previously prepared (210 mg, 0.307 mmol) in CH₂Cl₂ (0.250 mL) is diluted in acetic acid (2 mL). A solution of hydrogen bromide in acetic acid (33% w/w, 0.500 mL) is then added and a white precipitate appeared instantly. The mixture is vigorously stirred and heated at 70°C for 7 hours and then at room temperature overnight. The dark orange supernatant is removed by suction and the solid material is washed several times with Et₂O until a clear wash is obtained. The organic solvents are

completely removed first under reduced pressure and then by freeze-drying after solubilization in water to give the desired compound as a brownish solid material (200 mg, 0.288 mmol on the basis on an estimated PM 693.38 for 3HBr/4HBr hydrobromide forms in 85/15 *mol/mol* at *pH* 0.7⁴⁷). Yield (crude) 94%. The crude material can be purified by chromatography on RP18 (CH₃CN/H₂O 9/1 *v/v*) after raising the *pH* from 0.7 to about 4.5 (NaOH_{aq}) and leads to the desired product as a beige solid (115 mg, 0.221 mmol on the basis on an estimated PM 516.97 for .1HBr/.0HBr/.2HBr hydrobromide forms in 73/15/12 *mol/mol/mol* at *pH* 4.5⁴⁷). Yield 72%. ¹H NMR (D₂O, *pH*<1) δ (ppm): 3.14 (broad t, 2H, -CH₂-NH₂-); 3.20-3.38 (m, 6H, -N-CH₂-CH₂-NH-); 3.44 (broad s, 2H, -N-CH₂-CH₂-N-); 3.56 (broad t, 2H, -CO-NH-CH₂-); 4.00 (s, 2H, -N-CH₂-); 4.06 (s, 2H, -N-CH₂-); 4.47 (s, 2H, -N-CH₂-); 4.65 (s, 2H, -N-CH₂-); 4.80* (2H, -O-CH₂-CO-N-); 7.57 (d of AB system, J 8.4 Hz, 1H, CH_{Ar}); 7.71 (d of AB system, J 8.4 Hz, 1H, CH_{Ar}). *Fully superimposed with the deuterated solvent (deduced from corr ¹H/¹³C 2D experiment). ¹³C NMR (D₂O, *pH*<1): 36.6 (-CO-NH-CH₂-); 39.0 (-CH₂-NH₂-); 43.7, 43.9 (2 -N-CH₂-CH₂-NH-); 51.0, 52.2 (2 -N-CH₂-CH₂-NH-); 54.0, 56.7, 57.1, 57.4 (4 -N-CH₂-); 67.3 (-O-CH₂-CO-N-); 125.0 (2 CH_{Ar}); 142.1, 144.3, 152.0 (3 C_{quat}Pyr); 170.6, 172.2, 172.3 (2 CO₂, and -CO-NH-).

2-(12-[[2-aminoethyl]carbamoyl]methoxy)-9-(carboxymethyl)-3,6,9,15-tetraazabicyclo[9.3.1]pentadeca-1(15),11,13-trien-3-yl)acetic acid manganese *compound 17*:

A solution of the previously prepared ligand **16a.xHBr** (~0.17 mmol) in deionized H₂O (3 mL) is adjusted to *pH* ~ 5.5 with an aqueous solution of NaOH. Manganese(II) chloride tetrahydrate (33 mg, 0.168 mmol) is added in one portion which immediately induced a decrease of *pH* down to 2.2. The *pH* is carefully adjusted again to ~ 5.7 with aqueous NaOH. The resulting mixture is stirred at room temperature for 5 minutes. A monitoring by MS indicated a total conversion to

the desired manganese complex with no trace of free ligand **8**. The pH is then raised up to ~ 7.5 (NaOH_{aq}) and stirring maintained overnight. The fine brown precipitate formed is filtered off over a $0.2 \mu\text{m}$ membrane (PALL[®], Acrodisc[®]). The filtrate is concentrated by freeze-drying. The solid obtained (113 mg) is purified by chromatography on RP18 (MeOH/H₂O 9/1 v/v) and leads to the desired product **17** as a beige solid (108 mg, x H₂O.y HCl or NaCl probable form(s)). ESI-LRMS m/z : 492.2 [M+H]⁺, 514.1 [M+Na]⁺.

Determination of Mn²⁺ concentration for relaxometric and ¹⁷O measurements

The detection of free manganese ions is performed with a test of xylenol orange: 300 μL of phosphate or acetate buffer, one drop of pyridine, one drop of the compound solution and one drop of xylenol orange (0.1 g per 100 mL). The color is pink or orange for phosphate or acetate buffer respectively without manganese ions and gets purple when free manganese ions are present. The solution is then treated with a Chelex[®] 100 resin (sodium form) to eliminate those free ions.

The Mn²⁺ concentration determination is performed either by relaxometry and ICP-AES, on samples digested with nitric acid. The first method consists in measuring the water paramagnetic longitudinal relaxation rate of the digested solution at 20 MHz. It is then compared to the paramagnetic relaxation rate of a 1 mM solution of free manganese ions (equal to 8 s^{-1} at 20 MHz and 37°C) in order to extract the manganese concentration.⁴ To ensure the results, ICP-AES measurements are also performed on Varian Liberty Series II, based on a Mn²⁺ calibration curve. The concentrations obtained respectively from ICP-AES or relaxometry methods are

respectively 1.80 and 1.76 mM (MnL_1H), 5.09 and 5.66 mM (MnL_2COO^-), 7.85 and 8.05 mM (MnL_3CH), and 2.47 and 2.35 mM ($\text{MnL}_4\text{NH}_3^+$).

Relaxometry measurement

The longitudinal relaxation times (T_1) are determined at 20 MHz and 60 MHz on Bruker® Minispec mq20 and mq60 relaxometers. These measurements allow to obtain the relaxivity of

the complexes according to the following equation $r_1 = \frac{\left(\frac{1}{T_1 \cdot 10^{-3}}\right) - R_{1(\text{water})}^d}{[\text{Mn}_{\text{complex}}^{2+}]} \text{ s}^{-1} \cdot \text{mM}^{-1}$ (3) where

$$R_{1(\text{water})}^d = 0.2826 \text{ s}^{-1} \text{ at } 37^\circ\text{C}.$$

The NMRD profiles were recorded at 37°C and 25°C on a Stelar® fast field cycling (FFC) relaxometer (Stelar, Mede, Italy) and the least-squares fitting of the data was performed using a home-made program (Fitting2000) and equations from the Solomon and Bloembergen (SBM) theory.

Temperature dependent ^{17}O NMR measurements

The transverse ^{17}O relaxation rates ($R_2=1/T_2$) are measured in aqueous solutions of each manganese complex (MnL_1H ; 2.06 mM, MnL_2COO^- ; 2.58 mM, MnL_3CH : 2.05 mM and $\text{MnL}_4\text{NH}_3^+$: 1.21 mM) in the temperature range 7 – 81°C, on a Bruker® AvanceII-500 (11.75 T, 67.8 MHz) spectrometer. The temperature is calculated according to a previous calibration with ethylene glycol and methanol. Proton decoupling is applied during all the acquisitions. Transverse relaxation times (T_2) are obtained by the measurement of the signal width at mid-height. For the determination of τ_M , the data are presented as the reduced transverse relaxation

rate $R_2^R = 1/T_2^R = 55.55 R_2^P / ([Mn_{\text{complex}}] \cdot q)$, where $[Mn_{\text{complex}}]$ is the molar concentration of the complex, q is the number of coordinated water molecules and R_2^P is the paramagnetic transverse relaxation rate obtained after subtraction of the diamagnetic contribution from the observed relaxation rate. The treatment of the experimental data is performed as already described and the fitting of the data is obtained with a home-made program.⁴⁶

For the determination of the number of coordinated water molecules, the data are presented as the transverse relaxivity $r_2 = R_2^P / [Mn_{\text{complex}}]$ where the concentration of the Mn_{complex} is expressed in millimolar ($\text{mmol} \cdot \text{L}^{-1}$).

Transmetalation

The transmetalation is performed in a phosphate buffer solution (pH 7.06, salt concentrations below) and on the Bruker[®] Minispec mq20 relaxometer. 300 μL of a solution of each complex at a concentration of 2.5 mM is prepared in phosphate buffer solution ($[\text{NaH}_2\text{PO}_4] = 0.026 \text{ mol/L}$ et $[\text{Na}_2\text{HPO}_4] = 0.041 \text{ mol/L}$) and 3 μL of a solution 250 mM of ZnCl_2 (1 eq) is added in the studied Mn-complexes solutions. Then, the longitudinal relaxation time (T_1) is measured as a function of time to obtain the evolution of R_1^P following the equation: $R_1^P = \left(\frac{1}{T_1 10^{-3}} \right) - R_{1(\text{water})}^d$ (4) where $R_{1(\text{water})}^d = 0.2826 \text{ s}^{-1}$ is the diamagnetic contribution. During 5 days, the ratio $R_1^P / R_{1(t=0)}^P$ is determined at regular intervals to evidence the transmetalation kinetics induced by the presence of zinc cations, which leads to a release of manganese ions and their precipitation by phosphates. This release induces formation of a precipitate of $\text{Mn}_3(\text{PO}_4)_2$, which leads to a decrease of the paramagnetic relaxation rate.⁴¹

47. Note: Chemicalize was used for prediction of pK_as and speciation curves (December, 2019; <https://chemicalize.com/>, developed by ChemAxon): at highly acidic pH<1, species charged +3 and +4 are predominant for compound **16a** (85%, and 15% respectively at pH 0.7); at pH 4.5 (chromatographed solution), species charged +1, neutral, and charged +2 are predominant for compound 16a (73%, 15%, and 12% respectively).

Table of contents Graphic

Table of contents synopsis

Step-by-step synthesis of manganese complexes based on the pyclyen structure with a functionalized arm present on the pyridine moiety, as an alternative to gadolinium complexes as MRI contrast agents. This functionalized arm will allow the coupling of different molecules of interest for specific applications. A complete physicochemical characterization of the synthesized molecules is presented.
