HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Nonlinear Polarization Dynamics of VCSEL with Frequency Comb Injection

Abstract:

We propose a new approach of broad frequency comb generation by exploiting the polarization dynamics in a VCSEL induced by parallel frequency comb injection. Polarization mode competition leads to two tunable combs with orthogonal polarization. © 2021 The Author(s)

1. Introduction

Vertical-Cavity Surface-Emitting Lasers (VCSELs) have attracted significant attention due to their advantage of compactness, low cost, and low energy consumption and opens the possibility of mass production. VCSELs can show interesting polarization dynamics under optical injection [1]. It has been recently demonstrated that VCSEL can show complex polarization dynamics even in free running [2]. Recent experimental and theoretical analysis of polarization dynamics of VCSEL demonstrated the possibility of generation of two polarization comb under gain switching [3]. The quality of these combs obtained by gain switching depends strongly on the modulation frequency. The polarization combs properties have been found to improve with optical injection into the comb. The opposite situation in which a single-mode VCSEL is injected with an OFC has not been addressed so far. Recently, Optical frequency comb (OFC) injection in a diode laser has attracted significant attention [4, 5].

In this work, we analyze the polarization dynamics of a VCSEL subject to a narrow OFC injection. More specifically, we exploit the polarization dynamics of a VCSEL to generate a broad OFC with one or two polarization.

2. Experimental setup

Fig. 1. (a) set up for OFC injection into a VCSEL. TL: Tunable Laser, EDFA: amplifier, PC: Polarization Controller, AWG: Arbitrary Waveform Generator, MZM: Mach-Zehnder Modulator, VOA: Variable Optical Attenuator, BOSA: Brillouin Optical Spectrum Analyser. Figure 1 (b) and (c) shows the optical spectra of the free-running VCSEL and the injected comb, respectively.

Figure 1 (a) shows the setup for an OFC injection. The tunable laser output is amplified with an amplifier (EDFA). Electric signal modulation is generated by an Arbitrary Waveform Generator (AWG) and sent to the RF port of a Mach-Zehnder Modulator (MZM). An optical comb with 3 optical frequency lines is generated in the output of the MZM (see Fig. 1 (c)). The comb's optical power is controlled using a variable optical attenuator (VOA). The injected laser is a single-mode VCSEL with the dominant (X-PM) and depressed (Y-PM) polarization mode, respectively (see Fig. 1 (b)). The optical injection is performed through a fiber circulator. The injected laser dynamics are analyzed with a BOSA. A Polarized beam splitter (PBS) is used to separately observe the dynamics

of each polarization mode. The polarization controllers (PC) allows to align the laser polarization with the MZM, the VCSEL polarization with the axis of a (PBS), and to control the polarization of the injected light.

3. Results

Figure 2 (a) and (b) shows the optical spectra when the polarization of the injected OFC is turned to be parallel to that of the VCSEL. When varying the detuning for fixed injected power P_{inj} , the VCSEL output shows a time-periodic dynamics corresponding to an OFC with the same comb spacing as the injected comb in X-polarization mode (X-PM) (Fig. 2 (a)). When we keep varying the detuning, the VCSEL bifurcates to more complex dynamics in both polarization modes accompanied by an overall OFC generation as shown in Fig. 2 (b). We checked that

Fig. 2. (a), (b) optical spectra of VCSEL output for fixed comb spacing to $\Omega = 4 \text{ GHz}$. (a) and (b) are obtained for $P_{inj} = 432.8 \mu\text{W}$ and detuning $\Delta\nu = -2.6 \text{ GHz}$ and $\Delta\nu = -5.4 \text{ GHz}$, respectively. (c) OFC performance analysis for fixed $\Delta\nu = -0.9 \text{ GHz}$.

this OFC is formed by two micro-OFC with orthogonal polarization modes.

Figure 2 (c) analyzes the performance of the combs when varying the injected power for fixed detuning $\Delta\nu = -0.9 \text{ GHz}$. We qualify the comb quality by the number of lines (bandwidth) and Carrier to Noise Ratio (CNR). The CNR is the difference between the maximum amplitude in the optical spectrum and the noise level in dB. When increasing P_{inj} , the number of lines increases to achieve a maximum of around $P_{inj} = 400 \mu\text{W}$ while the CNR decreases. When varying the injection parameters, our data shows the possibility to control the comb spacing through harmonic OFC generation. Harmonic OFCs with repetition rates of hundreds of MHz can be indeed demonstrated. Figure 2 (c) shows also that the best CNR is found for low P_{inj} . We also check that the performance of the OFC dynamics improves with the bias current.

Numerical simulations are performed to analyze the impact of birefringence of the VCSEL on the two polarization OFC dynamics. Interestingly, we found that the resulting number of lines increases with the birefringence. Our theoretical results also predict that the comb lines of each polarization mode are phase-locked.

4. Conclusion

We have shown that injection of an OFC into a VCSEL induces interesting polarization dynamics leading to very wideband OFCs. Optimization of the injection parameters allows achieving a resulting comb bandwidth up to 13 times that of the injected comb and a Carrier to Noise Ratio (CNR) up to 60 dB. These results can be used for polarization division multiplexing for optical data communications and dual-comb spectroscopy.
