Synthesis and Spectral Properties of 6'-Triazolyl-Dihydroxanthene-Hemicyanine Fused Near-Infrared Dyes

Lingyue Gu,^a Kevin Renault,^b Anthony Romieu,^{*b} Jean-Alexandre Richard^{*c} and Rajavel Srinivasan^{*a}

We describe the synthesis of a range of 6'-triazolyl-dihydroxanthene-hemicyanine (DHX-hemicyanine) fused dyes through an effective copper-catalyzed azide-alkyne cycloaddition (CuAAC) "click" reaction, with the aim of providing molecular diversity and evaluating spectral properties of these near-infrared (NIR)-active materials. This was implemented by reacting 15 different aliphatic and aromatic azides with a terminal alkynyl-based-DHX-hemicyanine hybrid scaffold prepared in four steps and 35% overall yield from 4-bromosalicylaldehyde. The resulting triazole derivatives have been fully characterized and their optical properties determined both in organic solvents and simulated physiological conditions (phosphate buffered saline containing 5% of bovine serum albumin protein). This systematic study is a first important step towards the development of NIR-I fluorogenic "click-on" dyes or related photoactive agents for light-based diagnostic and/or therapeutic applications.

Introduction

The essence of "click chemistry" reactions lies in their simplicity, speed and robustness even in aqueous media.¹ While the concept has found popularity in organic chemistry, material science² and drug discovery,³ it comes as no surprise that biologists have also embraced it to perform chemistry in living systems (known as *in vivo* chemistry).⁴ By doing so, a new field coined bioorthogonal chemistry emerged and aims at developing advanced chemistry tools for the rational modification of biomolecules helping to a better understand of biology.⁵ Of particular interest is the labelling of biomolecules monitoring their activity and leading to the discovery and/or deciphering of new biological mechanisms.

In this context, the association of reactions belonging to the repertoire of "click chemistry" with organic-based fluorophores

has propelled the field of bioorthogonal chemistry to an indispensable tool for the optical imaging of biological systems.⁶ For instance, Meldal,⁷ Sharpless and co-workers⁸ rejuvenated the Huisgen 1,3-cycloaddition⁹ and reported a regioselective Cu-catalyzed version (known as CuAAC for copper-catalyzed azide-alkyne cycloaddition) which has become the most iconic "click" reaction known so far.¹⁰ Wang and co-workers applied it to fluorescent molecules and reported CuAAC reaction between 3-azidocoumarins and acetylenes.¹¹ While the aryl azide precursor did not display any fluorescence properties, the study showed that some of the triazoles formed turned fluorescent. In a similar fashion, Bertozzi's group used an azido aryl moiety as C9-substituent of xanthene-based fluorophores.¹² The initial azido rosamine did not emit any light because of a photoinduced electron transfer (PeT)-mediated quenching process. However, after evaluation of different positions of the azido group and electronic density of the aromatic ring, the fluorescence of the resulting triazole could be enhanced up to 58-fold (Scheme 1A).¹³ Kele's group also used aryl azide precursors¹⁴ but the approach using these scaffolds as fluorogenic precursors is limited because of their relative light instability and propensity to form the corresponding nitrene. It is possible to take advantage of this mechanism in the design of photoreactive cross-linkers suitable for photoaffinity labeling¹⁵ but in the context of the development of fluorogenic probes that instability is a serious limitation.¹⁶ One way around the need for an aryl azide precursor is to use a more stable terminal alkynyl-containing fluorophore. When the carbon-carbon triple bond replaces electron-donating groups (typically, *N,N*-dialkylamino moieties) it can turn the fluorophore to weakly or not fluorescent. This strategy was demonstrated by Tung's group on benzothiazoles¹⁷ and by Yao and co-workers on

rosamine- and xanthone-based fluorophores which displayed an increase of fluorescence emission upon formation of the triazole ring (Scheme 1B).¹⁸

Despite the advantages of longer-wavelength fluorescence light, known to facilitate molecular imaging in complex biological systems,¹⁹ such strategies have mostly been implemented with fluorophores emitting in the visible spectral range and little progress has been made so far on the development of similar near-infrared (NIR)-emitting dyes (specifically, within NIR-I optical window 650-900 nm). Over the years, our respective groups have designed chemical methods leading to the development of a novel class of NIR-I dyes based on a molecular hybrid scaffold that combine both structural features of xanthene and cyanine parent compounds.²⁰ These dihydroxanthene (DHX)-hemicyanine fused fluorophores are now regarded as attractive alternatives to the popular and commonly used polymethine-cyanine dyes, as illustrated by numerous and valuable achievements in the fields of biosensing, bioimaging and theranostics.²¹ Attracted by the modularity and ease of chemical modification of DHX-hemicyanine hybrid dyes, we set out to develop the access to a DHX precursor allowing the facile "click" formation of triazoles.

In a first attempt toward this goal, the introduction of an azido group on the 6'-position of the DHX skeleton proved to be a dead-end because of the marked photosensitivity of the aryl azide obtained. Instead, we took inspiration from our previous work to prepare an alkynyl-based DHX precursor **1** from the corresponding aryl bromide.²² We then explored CuAAC reaction with aliphatic and aromatic azides. Finally, we determined the spectral properties of the resulting "clicked" fluorophores **2a-2o** to assess the influence of both triazole moiety and its substitution pattern on NIR absorption/emission ability of fused DHX-hemicyanine scaffold (Scheme 1B). Details of these investigations and their possible extensions are discussed in the present Article.

Scheme 1 CuAAC reaction for the development of fluorogenic "click-on" dyes. A) Reaction of 3-azidocoumarin and Si-rosamine fluorogenic dyes with terminal alkynes; B) Reaction of alkynyl-based xanthone and DHX fluorogenic dyes with azido compounds.

Results and discussion

Synthesis of a library of 6'-triazolyl-dihydroxanthene-hemicyanine fused dyes

We started our study with the preparation of the alkyne "click" partner **1** which we readily obtained in two steps from bifunctional arylbrominated aldehyde **6** (Scheme 2). This latter DHX-hemicyanine precursor was prepared in two steps from 3-bromophenol **3** through (1) Casnati-Skattebøl *ortho*-formylation ($MgCl_2$, $(HCHO)_n$, NEt_3)²³ that provided 4-bromosalicylaldehyde **4** in 69% yield, and its subsequent (2) one-pot reaction with enal **5** to form the DHX skeleton **6**. The aryl bromide moiety was then reacted with trimethylsilylacetylene **7** under Sonogashira reaction conditions ($Pd(PPh_3)_4$, CuI , 79% yield).²² After removal of the TMS group under conventional conditions (K_2CO_3 , CH_3OH), the formyl group was reacted with 1,2,3,3-tetramethyl-3*H*-indol-1-ium iodide (Fisher's base) **10** to yield the desired alkynyl-based DHX-hemicyanine fused dye **1** in 88% yield over two steps. The structure was proven by NMR and ESI mass analyses and the high level of purity (>94% whatever the wavelength used for the UV-vis detection) was confirmed by RP-HPLC-based analytical control (see ESI†).

Scheme 2 Preparation of the alkynyl-based DHX-hemicyanine fused dye **1** in five steps from 3-bromophenol **3**.

We next explored reaction conditions allowing the formation of the desired triazole ring at the 6' position of the DHX-hemicyanine fused dye (Scheme 3A). To this end, we optimized the reaction conditions at room temperature in the presence of (3-azidopropyl)benzene **11a** as azido "click" partner, sodium ascorbate and various copper sources. While the use of copper(II) chloride and copper(II) sulfate pentahydrate provided some product (10% and 13% yield, respectively, Scheme 3A, entries 1-2), copper(II) acetate, copper(II) triflate and copper(I) chloride were much less successful (Scheme 3A, entries 3-6). Other usual "click" conditions using copper(I) sources without sodium ascorbate didn't provide any promising result either (Scheme 3A, entries 6 and 9). However, switching from the commonly used *tert*-butanol/water mixture of solvent to pure water in the presence of sodium ascorbate improved the yield significantly from 13% to 38% (Scheme 3A, entries 2 and 7). Ultimately, a mixture of DCM and water (Scheme 3A, entry 8) and 10 h reaction time appeared to be optimal (Scheme 3A, entries 10-12). With an interesting 50% yield (Scheme 3A, entry 8) it allowed us to explore the scope of the reaction with a wide range of alkyl and aryl azides **11b-o** (see ESI[†] for their synthesis).

B) Scope of the synthesis of triazole-based DHX-hemicyanine hybrids

Scheme 3 A) Optimization of the CuAAC reaction for the synthesis of 6'-triazolyl-DHX-hemicyanine fused dyes **2**; B) Scope of the CuAAC reaction using aliphatic and aromatic azides.

With one less carbon in its alkyl chain, (2-azidoethyl)benzene **11b** behaved similarly to azide **11a** and formed the corresponding triazole **2b** in 52% yield. 4-Chloro- and 4-methoxybenzyl azide **11c** and **11d** were also successful (the corresponding triazoles **2c** and **2d** were isolated in 74% and 36% yields, respectively) and the two 2-(azidomethyl)pyridines **11e** and **11f** developed by the Ting group to speed-up the CuAAC reaction *in cellulo* gave triazole cycloadducts **2e** and **2f** in good 81% and 61% yields, respectively.²⁴ The availability of triazole-based fluorophores bearing an extra functional group for structural tuning or covalent conjugation to other (bio)molecular partners is of great interest for biological applications. The CuAAC reaction was therefore achieved with **11g**, **11i**, **11m** and **11n** to introduce either a latent carboxylic acid (masked as methyl ester) or an aryloxysulfonyl fluoride moiety (this latter one being identified as an effective reactive

partner in "click" reaction sulfur(VI) fluoride exchange (SuFEx)²⁵). The possible influence of an electron-donating or -withdrawing substituent introduced on triazole moiety, over spectral properties of the resulting "clicked" DHX-based dyes, was also addressed through the successful synthesis of **2h-2l**. Finally, the presence of an *ortho*-substituted sulfonic acid group in **11o** provided a simple way to introduce a polar group facilitating the water-solubilization of the resulting DHX-hemicyanine fused dye **2o** (Scheme 3B). The structures of these 15 novel triazole-based DHX-hemicyanine fused dyes were unambiguously confirmed by ESI-HRMS and NMR spectroscopic analyses (see ESI[†]). Their purity was checked by RP-HPLC and found to be above 95%, value usually required to achieve relevant photophysical measurements.

Photophysical properties of 6'-triazolyl-dihydroxanthene-hemicyanine fused dyes

To assess changes in photophysical properties after triazole formation, we next studied the spectral behavior of our library of 15 DHX-hemicyanine fused dyes **2a-2o** and alkynyl precursor **1** in different media including phosphate buffered saline (PBS) with 5% (w/v) bovine serum albumin (BSA) as simulated body fluid, EtOH, and CHCl₃ (Table 1 and Fig. 1 for the Abs/Ex/Em spectra of **1** and **2o** in CHCl₃ and in PBS + 5% BSA, see ESI[†] for Abs/Ex/Em spectra of other compounds). A first general trend common to all triazole-based dyes and alkyne **1** is the dramatic broadening of the main absorption band assigned to S₀-S₁ electronic transition, compared to that of more conventional DHX-hemicyanine fused fluorophore bearing a *N,N*-dialkylamino group as C-6' substituent like **12**, which explains the notable lower molar extinction coefficient of dyes **2a-2o** compared to **12**. A full-width half maximum (FWHM), $\Delta\lambda_{1/2 \text{ max}}$ in the range of 3410-4370 cm⁻¹ is observed depending primarily on the solvent used, against only 695-990 nm for **12** and unlike the latter, well-defined vibronic structures with two maxima and one pronounced blue-shifted shoulder are observed in all absorption spectra. The lack of an effective electron-donating group such as -NEt₂, on C-6' position, induces an expected hypsochromic shift of ca. 50 nm or 100 nm depending the local absorption maximum regarded for the triazole derivatives, of the maximum absorption peak position for the DHX-hemicyanine hybrid scaffold. This feature also contributes to the dramatic decrease of molar extinction coefficients compared to those of more conventional DHX-based fluorophores such as **12**.

Red excitation at 620 nm produced the desired NIR emission in the form of a vibronic structure with two well-defined maxima in the range 690-760 nm. However, only a very weak fluorescence emission intensity was observed, whatever the triazole derivative studied, the solvent and concentration range (1-10 μ M) used. It prevented us to accurately determine relative fluorescence quantum yields, roughly

Fig. 1 Normalised absorption, emission (excitation at 620 nm for a-d and 650 nm for e-f) and excitation (emission at 760 nm for a-d, 830 nm for e or 800 nm for f) spectra of alkynyl-based DHX-hemicyanine fused dye **1** (a in CHCl₃ and b in PBS + 5% BSA), triazole-based DHX-hemicyanine fused dye **2o** (c in CHCl₃ and d in PBS + 5% BSA), and *N,N*-diethylamino-DHX-hemicyanine fused dye **12** (e in CHCl₃ and f in PBS + 5% BSA). For the excitation spectrum of **12** in PBS + 5% BSA, a peak at 400 nm ($\lambda_{ex}/2$) assigned to Rayleigh scattering is observed. See the Experimental section for details about these measurements.

estimated at less than 1%. The very low values of these quantum yields cannot be attributed to the formation of non-emissive aggregates (*i.e.*, H-type homodimers)²⁶ because a good matching between the absorption and excitation spectra was observed except for some triazole derivatives (*e.g.*, **2i**, **2l** and **2m**, see ESI[†]) and **1** spectrally characterised in simulated physiological conditions (*i.e.*,

PBS + 5% BSA). The capability of BSA protein to disrupt fluorophore aggregates in aq. media is well-documented but in the present case, its surfactant behavior was not sufficiently effective to obtain a single emissive species in solution.²⁷ Alternatively, we attempted to assess the relative fluorescence efficiency of dyes **2a-2o** and **1** by calculating the ratio [(integration of emission curve)/absorption at 620 nm]] for

a single concentration (5 μ M) solution in CHCl_3 of each compound (**1** and **2a-2o**). We observed a change in color of solution from sapphire blue (for alkyne **1**) to sky blue (for triazole derivatives **2a-2o**) (see ESI†) but could not obtain reliable values allowing an accurate and relevant ranking of the fluorophores synthesized in this study, based on their emissive capability.

Conclusions

Quest for high-performance NIR-I chromophores/fluorophores based on the attractive DHX-hemicyanine hybrid scaffold led us to consider for the first time CuAAC "click" reaction as a simple way of achieving high molecular diversity through the straightforward synthesis of alkynyl-based DHX-hemicyanine fused dye **1** and its "click" derivatisation with a wide range of organic azides. In contrast to already published fluorogenic alkynes photoactive in the blue-green spectral range, only a weak fluorescence emission of triazole-based dyes was observed within the NIR-I window. Thus, our efforts that involved synthesis and photophysical characterization of a library of 15 different compounds will require a further structural optimization to obtain NIR-I fluorogenic "click-on" dyes suitable for bioimaging. Interestingly, the specific molecular absorption signature of both alkyne and triazole derivatives (*i.e.*, broad, structured and weakly solvent dependent absorption band) might be used to design novel broad spectrum dark quencher molecules suitable for the construction of far-red or NIR-I fluorescence light-up probes based on Förster resonance energy transfer (FRET) mechanism.²⁸

Synthesis

6-((Trimethylsilyl)ethynyl)-2,3-dihydro-1H-xanthene-4

carbaldehyde (8). Pd(PPh₃)₄ (67.5 mg, 8.3 mmol%) and CuI (23.6 mg, 0.1 mmol) were degassed in a flame-dried round bottom flask. NEt₃ (1.2 mL, 8.3 mmol) in dry DMF (10 mL) was added with aryl bromide **6** (1.2 g, 4.1 mmol). The solution was degassed again then trimethylsilylacetylene **7** was added (1.8 mL, 12.4 mmol). The reaction mixture was heated to 85 °C for 24 h. After being cooled to room temperature, the reaction mixture was concentrated under vacuum and the resulting residue was purified by flash-column chromatography on silica gel (eluent: 1% EtOAc in PE) affording pure TMS-protected terminal alkyne **8** as a orange solid (1.0 g, yield 79%). ¹H NMR (400 MHz, CDCl₃): δ = 10.30 (s, 1 H), 7.17 (s, 1 H), 7.13 (dd, J = 7.8 Hz, J = 1.2 Hz, 1 H), 7.05 (d, J = 7.8 Hz, 1 H), 6.62 (s, 1 H), 2.58 (ddd, J = 7.5 Hz, J = 5.8 Hz, J = 1.6 Hz, 2 H), 2.43 (t, J = 6.0 Hz, 2 H), 1.71 (m, 2 H), 0.25 (s, 9 H); ¹³C NMR (101 MHz, CDCl₃): δ = 188.0, 159.9, 151.7, 130.8, 127.6, 126.5, 126.1, 124.6, 121.6, 118.6, 113.8, 104.0, 96.9, 30.3, 21.6, 20.4, 0.0 ppm; HRMS (ESI+): m/z 331.1141 [M + Na]⁺, calcd for C₁₉H₂₀O₂SiNa⁺ 331.1125.

6-Ethynyl-2,3-dihydro-1H-xanthene-4-carbaldehyde (9). TMS-protected terminal alkyne **8** (1.0 g, 3.3 mmol) was dissolved in dry MeOH (30 mL) and treated with anhydrous K₂CO₃ (1.8 g, 13.2 mmol). The mixture was stirred at room temperature for 5 h. The solvent was removed, and the residue was taken up in 100 mL of DCM and washed with 100 mL of deionised water. The organic layer was dried over anhydrous Na₂SO₄ and concentrated under reduced pressure. This compound was used in the next step without further purification, and the yield was assumed to be quantitative. ¹H NMR (400 MHz, DMSO-*d*₆): δ = 10.26 (s, 1 H), 7.36 (d, J = 7.9 Hz, 1 H), 7.34 (s, 1 H), 7.24 (dd, J = 7.8 Hz, J = 1.5 Hz, 1 H), 7.01 (s, 1 H), 4.37 (s, 1 H), 2.59 (ddd, J = 7.0 Hz, J = 5.3 Hz, J = 1.6 Hz, 2 H), 2.30 (t, J = 6.0 Hz, 2 H), 1.63 (m, 2 H) ppm; ¹³C NMR (101 MHz, CDCl₃): δ = 188.1, 159.8, 151.7, 131.1, 127.7, 126.6, 125.9, 123.6, 122.0, 118.9, 113.9, 82.8, 79.3, 30.3, 21.6, 20.4 ppm; HRMS (ESI+): m/z 237.0910 [M + H]⁺, calcd for C₁₆H₁₃O₂⁺ 237.0910.

Alkynyl-based DHX-hemicyanine fused dye (1). To aldehyde **9** (236 mg, 1.0 mmol) in EtOH (2 mL) was added 1,2,3,3-tetramethyl-3H-indol-1-ium iodide **10** (301 mg, 1.0 mmol) and the solution was refluxed at 80 °C for 4 h. The reaction mixture was concentrated and the crude product was purified by flash-column chromatography on silica gel (eluent: 1% MeOH in DCM) to afford alkynyl-DHX **1** as a dark blue solid (345 mg, yield 88%). m.p >300 °C; ¹H NMR (400 MHz, DMSO-*d*₆): δ = 8.56 (d, J = 15.3 Hz, 1 H), 7.80-7.73 (m, 2 H), 7.62 (s, 1 H), 7.58 (m, 1 H), 7.52 (m, 2 H), 7.39-7.33 (m, 2 H), 6.68 (d, J = 15.4 Hz, 1 H), 4.52 (s, 1 H), 3.95 (s, 3 H), 2.72 (t, J = 6.0 Hz, 2 H), 2.67 (t, J = 6.0 Hz, 2 H), 1.83 (m, 2 H), 1.77 (s, 6 H) ppm; ¹³C NMR (101 MHz, DMSO-*d*₆): δ = 179.0, 158.0, 151.8, 145.1, 142.4, 142.1, 131.1, 129.8, 128.8, 128.4, 127.8, 127.6, 123.8, 122.6, 122.2, 118.6, 114.3, 113.8, 107.2, 83.8, 82.6, 50.8, 33.2, 28.7, 26.9, 23.5, 19.7 ppm; HRMS (ESI+): m/z 392.2019 [M]⁺, calcd for C₂₈H₂₆NO⁺ 392.2009; HPLC (system A): t_R = 4.9 min (purity 94% at 260 nm and 98% at 600 nm); LRMS (ESI+, recorded during RP-HPLC analysis): m/z 392.3 [M]⁺ (100), calcd for C₂₈H₂₆NO⁺ 392.2; UV-vis (recorded during the HPLC analysis): λ_{max} = 559 and 592 nm (broad band).

General procedure for the synthesis of tetrazole-based DHX-hemicyanine fused dyes 2a-2o. To a mixture of alkynyl-based DHX-hemicyanine dye **1** (784 mg, 2.0 mmol, 1.0 equiv.) and the corresponding organic azide **11a-o** (2.6 mmol, 1.3 equiv.) in deionised water and CH₂Cl₂ (1:1 (v/v), 100 mL), sodium ascorbate (79.2 mg, 0.4 mmol, 0.2 equiv.) was added, followed by the addition of CuSO₄ • 5 H₂O (25 mg, 0.1 mmol, 0.05 equiv.). The heterogeneous mixture was stirred vigorously at room temperature overnight. Thereafter, the reaction mixture was concentrated under reduced pressure and directly purified by flash-column chromatography on silica gel (eluent: 1% MeOH in DCM) to afford the corresponding triazole **2a-2o** as a dark blue amorphous powder.

Photophysical characterisations

UV-visible spectra were obtained either on a Varian Cary 50 scan (single-beam) or an Agilent technologies 60 (single-beam) spectrophotometer (software Cary WinUV) by using rectangular quartz cells (Hellma, 100-QS, 45 × 12.5 × 12.5 mm, pathlength: 10 mm, chamber volume: 3.5 mL), at 25 °C (using a temperature control system combined with water circulation). Fluorescence spectra (emission/excitation spectra) were recorded with an HORIBA Jobin Yvon Fluorolog spectrofluorometer (FluorEssence software) at 25 °C (using a temperature control system combined with water circulation), with standard fluorometer

cells (Labbox, LB Q, light path: 10 mm, width: 10 mm, chamber volume: 3.5 mL). The absorption and fluorescence emission spectra were recorded with dye solutions of concentrations in the range of 10^{-5} – 10^{-6} M. The emission spectra were recorded in the range of 635–850 nm after excitation at 620 nm (shutter: Auto Open, integration time = 0.1 s, 1 nm step, HV(S1) = 950 V, excitation slit = 5 nm and emission slit = 5 nm). The excitation spectra were recorded in the range of 400–750 nm after emission at 760 nm (excitation slit = 5 nm for spectra recorded in CHCl_3 and 12 nm for spectra recorded in EtOH or PBS + 5% BSA and emission slit = 5 nm). All excitation/emission spectra are corrected.
