Abstract:

In this work, innovative biosourced polyimide polymers were derived from novel combinations of monomers (Isosorbide, 6-FDA and amine cardo). These polymers were obtained with satisfactory yields by polycondensation of different percentages of isosorbide and of 6-FDA (from 100% to 0%). The synthesized polyimides had number average molecular weight in the 17600 -22000 g/mol range, and they were stable well above 451 °C (5% weight loss in N₂). The glass transition temperature (T_g) were found to be in the range of 318 – 414 °C, depending on the composition of the copolymers. The adsorption of Water Framework Directive (WFD) heavy metals (Pb²⁺, Ni²⁺, Cd²⁺, Hg²⁺) on the biosourced polyimide films deposited on a gold electrode was monitored by the measurements of the impedance of the electrolyte/polyimide polymer/electrode interface. The adsorption isotherm of Pb²⁺ on the different polyimide films was modeled according to a Langmuir isotherm with a best fitting. The relative adsorption capacities were higher when the isosorbide content was higher. Comparing the adsorption capacities of the different WFD heavy metals of the isosorbide based polyimide, the sequence is the following one: Pb²⁺ ≈ Ni²⁺ > Cd²⁺ > Hg²⁺. These results are within the paradigm of Pearson's HSAB principle about the metal-oxygen interaction. When isosorbide based polyimide is the sensitive part of an impedimetric sensor, the detection limit for all the WFD

heavy metals is 50 pM, very lower than the environmental quality standards for these WFD priority hazardous substances.

Keywords: Bio-based polyimide polymers; Heavy metals; Isotherm model; Detection.

1. Introduction

Heavy metals for instance cadmium, lead, nickel and mercury, are subject to important health and environmental monitoring¹. They are emitted mainly from various industrial activities such as metal plating facilities, mining operations, fertilizer industries, tanneries, batteries, paper industries and pesticides, etc². Unlike organic contaminants, heavy metals are not biodegradable and tend to accrue in living organisms³. The accumulation of heavy metals can cause eminent health problems, such as serious toxicological concerns, central nervous system damage, impairment of pulmonary and kidney function⁴.

The Water Framework Directive (WFD) that governs European water policy cites four metals: lead, cadmium, nickel and mercury. The WFD has been placed as the main European regulation for the protection of the water resources⁵. One of its principal objectives is to achieve good chemical and ecological status and to restore and to preserve water bodies at a “good status”. Chemical status refers to specific pollutants (e.g., priority substances or priority hazardous substances) and environmental quality standards (EQS) are defined for them. Environmental Quality Standards (EQS) for Cd, Ni, Pb, and Hg are, respectively, 0.7-2.2, 341, 35, and 0.25 nM. As the WFD implementation gradually comes into effect in European countries, the environmental metrology and remediation become a big challenge.

Therefore, several laboratories have focused on the conception and development of efficient methods for the removal of these toxic ion pollutants such as ion-exchange⁶, chemical precipitation⁷, adsorption⁸, membrane filtration⁹ and electrochemical treatment technologies¹⁰.

In order to accurately assess contamination levels, a large number of analysis' methods and processes for the determination of trace substances were developed. These techniques are principally classified as optical techniques¹¹ and highly sensitive spectroscopic techniques¹². These later include atomic absorption spectroscopy (AAS)¹³, inductively coupled plasma mass spectroscopy (ICP-MS)¹⁴, neutron activation analysis (NAA), X-ray fluorescence spectrometry (XRF)¹⁵, laser induced breakdown spectroscopy (LIBS)¹⁶, ion chromatography (IC)¹⁷ and UV-Visible spectrometry (UV-VIS)¹⁸. These analytical techniques must combine selectivity and

high sensitivity while respecting many imperatives.¹⁹ However, these spectroscopic techniques are very expensive and complex and are not suitable for field application. Electrochemical sensors²⁰ can be considered as the best alternative because of their experimental simplicity, exceptional detectability, well suited for miniaturization and especially for their low cost. In this context, several electrochemical techniques²¹ have been advanced in the field of heavy metals detection such as cyclic voltammetry (CV)²², anodic stripping voltammetry (ASV)²³, square wave anodic stripping voltammetry (SWASV)²⁴, electrochemiluminescence (ECL)²⁵ or electrochemical impedance spectroscopy (EIS)²⁶. Nevertheless, these electrochemical techniques require development in the design to improve their performance in the detection of heavy metal ions, in particular the modification of the electrode²⁷ which is a problem linked to its reusability because the reduced deposited metal must be eliminated with aggressive solutions, not compatible with the on field use.

Recently, organic electrode materials have become a wise choice for the manufacture of electrodes because of their structural diversity, high specific capacity, renewability, lower cost and respect for the environment²⁸. Various technologies have been presented, using organic polymers such as polyaniline²⁹, polypyrrole³⁰, polythiophene³¹. In fact, polyimides (PI) are widely used thanks to their excellent overall properties, high thermal stability, suitable T_g, high mechanical resistance, high resistance to radiation and solvents, good optical, properties high breakdown voltage and easy processability as coatings or film³². As a consequence, they can find a wide range of various sensor applications³³: as the sensitive part for humidity sensors³⁴, as the substrate for pH sensors³⁵, as porphyrinated sensitive fluorescent part for hydrogen chloride gas sensors³⁶, as sensitive part for salinity sensors³⁷, as porphyrinated sensitive fluorescent part for trinitrophenol sensors³⁸ and as sensitive part for dopamine electrochemical sensors³⁹. Several types of polyimide polymers were identified for adsorption phases of heavy metal ions: poly(hydriazide-imide)s⁴⁰, poly(amide-hydrazide-imide)s⁴¹ and xanthone-based polyimides⁴². In this context, successful interactions between PI and metals ions are essential in the applications of sorbents and sensors. It is worth to note that the properties of PI are considerably affected by their source materials, including the types of diamines and dianhydrides, imidization processes and drying methods.

The challenge in this work consists on the synthesis and characterization of new partially biosourced polyimides derived from novel combinations of monomers (Isosorbide, 6-FDA and amine cardo), which can participate in the development of polyimides modified gold electrodes for the impedimetric detection of Cd, Ni, Pb and Hg. Copolymerization of the chosen

homopolyimides may result in the combination of the base properties of each homopolymer which can lead to improved separation performance of the resulting co-polymer. The incorporation of isosorbide into polymer can generate superior rigidity, high thermal property, biodegradability, attractive hydrophilicity and wettability, as well as non-toxicity⁴³. On the other hand, the presence of CF₃ in the 6FDA structure has a hydrophobic property in contrast to biosourced isosorbide and improves, in addition, the rigidity of the chain⁴⁴. In our study the amine cardo was introduced in all the elaborated polymers in order to improve thereby processability and solubility⁴⁵⁻⁴⁶.

The main aim of this study is to design new partially biosourced polyimides and copolyimides for the modification of gold electrodes. Each synthesized polymer was fully characterized using NMR spectroscopy, GPC, TMA and TGA. After the structural characterization and the thermal analysis, the adsorption properties of the polyimide modified electrodes were then monitored with electrochemical impedance spectroscopy⁴⁷.

2. Materials and Methods

2.1. Reagents and Standards

Isosorbide (98%, recrystallized from acetone), Sodium hydride (60 % dispersion in mineral oil), 4-nitrophthalonitrile (99 %), 2,2'-bis-(3,4'-dicarboxyphenyl) hexafluoropropanedianhydride (6FDA or (6)) (>99.0%), 4,4'-(9-Fluorenylidene) dianiline (CARDO or (7)) (99%) were purchased from Sigma-Aldrich. M-cresol (99%) were purchased from Acros Organics and all the other solvents were of analytical grade and used as received.

Solutions of metallic ions were prepared from standard solutions for AAS in nitric acid (Sigma-Aldrich). Potassium citrate tribasic monohydrate (98%) and ethylenediamine tetraacetic acid (EDTA, 99%) were purchased from Sigma-Aldrich.

2.2. Monomer Synthesis

The synthesis of dianhydride derived from isohexide was optimized according to a literature procedure⁴⁴ that comprised three steps as described in Figure 1.

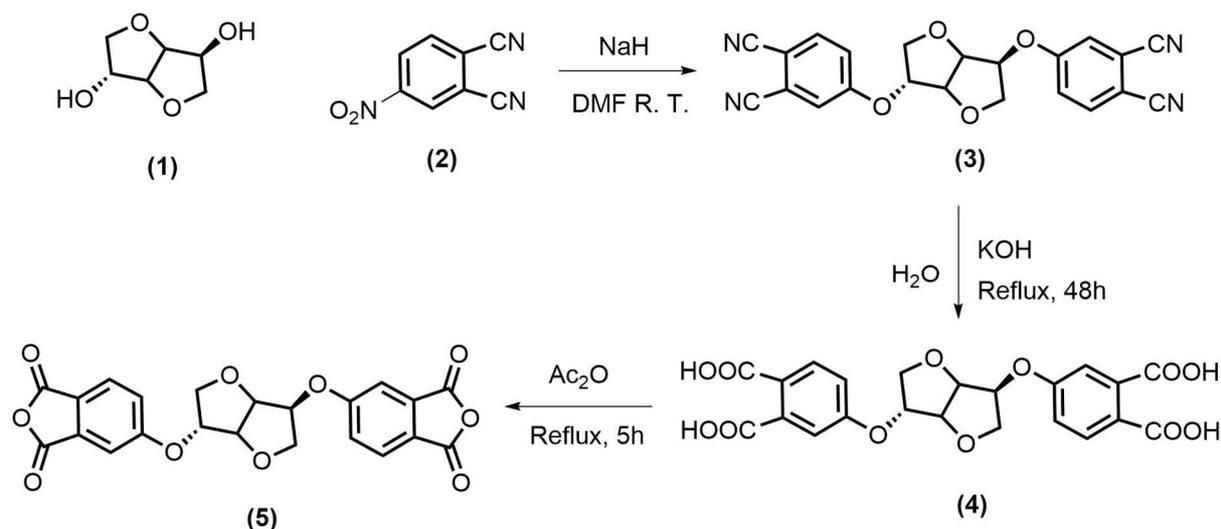

Figure 1: Preparative route for isohexide-derived dianhydrides (**5**)

2.2.1 Synthesis 1,4:3,6-dianhydro-2,5-bis-(3-4-dinitrile-phenyl)-D-sorbitol (**3**)

Isosorbide (**1**)(4.39 g; 30 mmol) and DMF (60 mL) were taken in a 150 mL three necked flask, which was equipped with a magnetic stirrer and a nitrogen inlet and outlet. The mixture was stirred at 0°C for 15min, Sodium hydride (2.65g; 65mmol) was added to the mixture. After stirring for 1h, 4-nitrophthalonitrile (**2**)(11.25g; 65 mmol) was introduced in small portions. The solution was stirred for 24h at room temperature and then the reaction mixture was poured in 100 mL of water. The aqueous layer was extracted three times with ethyl acetate, the organic fractions were combined, and dried over magnesium sulfate. The solvent was removed by rotary evaporation, and the solid was dried at 100°C under vacuum to afford (?). A yellowish powder was obtained. Yield : (11.95 g; 99%).

2.2.2 Synthesis of 2,5-bis(3,4-dicarboxyphenoxy)-1,4:3,6- dianhydrosorbitol (**4**)

The intermediate (**3**) (30 mmol, 11.95 g) was suspended in water (330 mL) with KOH (11 eq, 372 mmol, 12.45 g) in a two necked round bottom flask and stirred magnetically. The medium was warmed to 100 °C and the reaction was refluxed for 48 h. After completion (TLC control), the mixture was cooled to room temperature and a few drops of HCl (cc) were added up to precipitate formation. The addition was continued until acidic pH was reached (pH = 2–3). The aqueous layer was extracted three times with ethyl acetate, the organic fractions were combined, washed with water, and dried over magnesium sulfate. The solvent was removed by rotary evaporation, and the solid was dried under vacuum to afford. The acid was recovered as a yellow solid. Yield : (93 %).

2.2.3. Synthesis of 1,4:3,6- dianhydro-2,5-bis(3,4-dicarboxyphenoxy)- D-Sorbitol(**5**)

The monomer (5) was prepared by refluxing 10 mmol of tetra-acid in an acetic anhydride (25 mL) for 4 h at 120°C. Upon cooling, the residue was precipitated in diethyl ether (100 mL), was filtered and washed to obtain a beige powder. Yield: (92%).

2.3. Synthesis of polymers and copolymers

In this work, all polyimides were prepared via a conventional one-step method in m-cresol. A representative procedure follows. An equimolar amount of dianhydride and diamine monomers were used and m-cresol (cc 20%) was charged into a three-necked, round-bottomed, 25 mL flask equipped with a mechanical stirrer, and gas inlet and outlet. The reaction mixture was heated for 3h at 180°C under a mild nitrogen flow. After polymerization, the reaction mixture was cooled to room temperature, and precipitated into methanol. The fibrous precipitate was collected by filtration, washed with methanol, Soxhlet extracted with methanol for 24 h, and dried in vacuum at 120 °C for 24 hours to afford polyimides P1-P5.

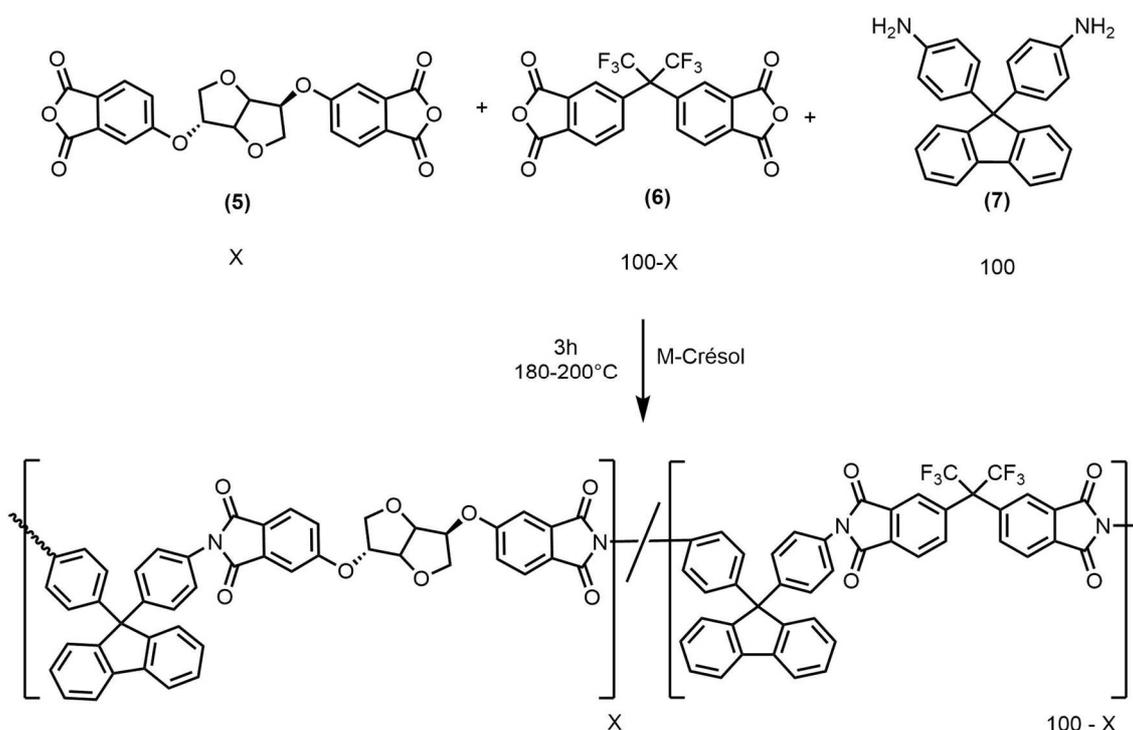

Figure 2: The synthetic routes of the homopolyimides and copolyimides P1-P5 (X=100, P1/ X=75, P2/ X=50, P3/ X=25, P4/ X=0, P5)

2.4. Characterization Methods

NMR spectra were obtained on a Bruker Advance 300 spectrometer (Bruker, Palaiseau, France), with frequencies of 300.1 and 75.5 MHz respectively for ^1H and ^{13}C analysis. The solvent used was DMSO-*d*₆ and tetramethylsilane (TMS) was used as internal reference.

Thermogravimetric analyses (TGA) were performed under nitrogen atmosphere at a heating rate of 10°C/min from 25 °C to 500 °C, using a TA Q50 Instrument (TA Instruments Division de Waters SAS, Guyancourt, France).

T_g were determined by thermomechanical analyses (TMA), with a TA Instruments model Q400, under nitrogen, at a heating rate of 10°C/min and in the penetration mode.

Molecular weights were determined by Size Exclusion chromatography (SEC) on a system equipped with a Shimadzu LC-20AD pump and a differential refractive index detector. CDCl₃ was used as eluent. SEC analyses were achieved with Waters Styragel columns (HR2+HR1+HR0.5). Reported values (number average molar masses (M_n), weight average molar masses (M_w) and chain disparities (PD) were determined from a polystyrene calibration curve.

2.4. Preparation of Polymer-Modified Gold Electrodes and Impedimetric Measurements

Gold substrates (300 nm of gold layer/ 30 nm of titanium layer/ 300 nm SiO₂/ p-type Si/300 nm SiO₂) were provided by the French RENATECH network (LAAS, CNRS Toulouse). The gold electrodes were 1.2 cm × 1.2 cm square plates. The gold surface was rinsed with acetone for 15 min, rinsed with ultrapure water then dried under nitrogen flow. Then it was alternately immersed for 2 mins freshly prepared hot piranha solution, rinsed with ultrapure water, and dried under nitrogen flow. After the surface treatment, 5 μL of 1w/w% chloroform solution of P1, P2, P3, P4 or P5 polymer was dropped on the electrode surface and then dried under nitrogen flow. Drop-coating was chosen because spin-coating was not applicable, due to the volatility of chloroform.

Electrochemical measurements were performed in a 5 cm³ Pyrex glass electrochemical cell equipped with the polymer-modified gold electrode (0.07 cm² active area, defined by an O-ring seal), as a working electrode, a platinum counter-electrode and a Ag/AgCl reference electrode. All measurements were carried out at room temperature (23 ± 3°C). When the polymer-modified gold electrode was in contact with the 0.1 M potassium citrate solution (pH 4.0) containing the metallic ions, the measurements were performed after 10 minutes of equilibration. Electrochemical Impedance Spectroscopy (EIS) measurements were operated using a potentiostat-galvanostat Voltalab 80 (Hach, Germany). In these experiments, an amplitude of 10 mV, with a frequency range of 100 mHz to 100 kHz, was superimposed to a dc voltage. The value of the dc voltage was the free potential of the modified electrode in 0.1 M potassium citrate solution at pH 4.0. The real and imaginary impedances were computed and a Nyquist plot was drawn. The impedance values were fitted, using Zview software from

Scribner Associates, to a standard Randles equivalent circuit consisting of a parallel combination of a constant phase element (CPE) and a Faradaic impedance Z_f in series with the solution resistance (R_s). The faradic impedance is a series combination of polarization resistance (R_p) and the Warburg impedance (W).

Surface morphology was observed by scanning electron microscopy (SEM)(VEGA TESCAN SEM).

3. Results and Discussion

3.1. Physicochemical Characterization of the Resulting Polymers P1-P5

The partially bio-based dianhydride monomer (5) was synthesized according to the route described in Figure 1 with high yield. This dianhydride derived from isohexide was synthesized according to a literature procedure with further optimization.

The general procedure adopted comprised three steps: firstly the nucleophilic substitution between the commercially available isosorbide and dinitroptalonitrile under the catalysis of sodium hydride, followed by hydrolysis with KOH, and subsequent dehydration using acetic anhydride. The structure and the high purity of the synthesized intermediate and monomer ((3), (4) and (5)) were confirmed by ^1H NMR analysis (representative NMR data presented in Figure S1).

Series of copolyimides were prepared from the synthesised bio-based dianhydride (5), the petrobased dianhydride (6) and the diamine (7) via one step polycondensation method in *m*-cresol at 180 °C which last 3 hours, as illustrated in Figure 2.

A set of five experiments with different feed ratios ((5) / (6)) were conducted each time (100/0, P1; 75/25, P2; 50/50, P3; 25/75, P4; 0/100, P5;). The resulting polymers were isolated by precipitation in methanol and were purified by extraction with methanol in a Soxhlet extractor, followed by drying in a vacuum during 24 h at 120 °C.

As shown in Table 1, the five synthesized polymers were obtained with good yields in the range of 72 -99%. All the resulting homopolyimides and copolyimides showed satisfactory molecular weight, indicated by their high number average molecular weight (M_n). These values comprised in the 17600-22000 g/mol range and with dispersity index (PD) between 4.03 and 4.79. For a given dianhydride, there was no significant difference in molecular weight values between (5) and (6) based polymers (M_n (P1) = M_n (P2) = 22000 g/mol). For the synthesized copolymers,

the GPC results indicated a slight decrease in the molecular weight of the copolyimides compared to the homopolyimides which is probably due to the stoichiometry and the difference in reactivity of the monomers introduced.

Table 1. Yields, compositions, molecular weights and thermal behaviors of resulting polymers P1-P5.

Ref.Polymer	Yield ^{a)} (%)	Composition (5) / (6)		Molecular weight			Tg ^{e)} (°C)			Td _{5%} ^{f)} (°C)
		Feed ^{b)}	polymer ^{c)}	M _n ^{d)}	M _w ^{d)}	PD ^{d)}

a)After precipitation into water and washing with methanol, evaporation under a vacuum at 120 °C.

b)Molar ratio in the initial feed.c)Molar ratio in the copolyimides determined by ¹H NMR.

d)Number and weight-average (M_n, M_w; in Da) molecular weights and polydispersity (PD) determined by GPC in CDCl₃ against polystyrene standards.

e)Determined by thermomechanical analysis TMA, under nitrogen, at a heating rate of 10°C/min and in the penetration mode.

f)Td_{5%}: temperature of 5% weight, determined by TGA, at a heating rate of 10°C.min⁻¹, with a nitrogen flow rate at 50 mL/min.

The chemical structures of the prepared polyimides were confirmed by ¹H NMR and ¹³C NMR and the results were in good agreement with the proposed structures. A detailed description of the NMR data recorded from homopolyimides and copolyimides are given in Figure S1.

As can be seen in the NMR spectra, the successful incorporation of isosorbide units into the polyimide chain were confirmed to be relatively quantitative by the group signals in the NMR spectra at 3.9-5.4 ppm (A detailed description are given in Figure S1). The resonance signals in the range of 7.81-8.11ppm were assigned to the aromatic protons of (6), protons of (7) as well as the aromatic protons from the monomer unit (5). The absence of end-groups on the NMR spectra clearly shows that these polyimides have a good molecular weight.

The incorporation of the monomers were observed to be relatively quantitative, confirming values of the molar ratio units in copolymers determined from integrated intensities of NMR signals of respective protons

The ¹H NMR spectroscopy technique was also helpful to calculate the actual molar composition of monomers compared to the initial feed ratios. The molar composition, presented in Table 1, state the proportion of (5) and (6) monomers in the copolyimides structure. The calculation of

the ratios is founded on the integration of experimental NMR proton signals characterizing each of the two monomers that gives indication about the structural composition.

Results of these characterization methods were collected in Table 1. These calculated values based on ^1H NMR analysis agreed with the introduced feed ratios. The molar ratio in the copolyimides determined by ^1H NMR. values indicate a very slight difference compared to those of the molar ratio in the initial feed, in favor of the repeating unit of isosorbide. This can be explained by the higher reactivity of isosorbide compared to 6-FDA.

The study of the thermal behavior of the synthesized polyimides enlarges their potential application feed. The thermal properties of the polymers were investigated by thermogravimetric analyses (TGA) and thermomechanical analysis (TMA).

The glass transition temperatures of polyimides were carried out via thermomechanical analysis (TMA) and the results are listed in Table 1. Homopolymers revealed a single glass transition displayed at 318 °C and at 387°C. The homopolymer based on 6-FDA presents a higher temperature which is due to its structure more rigid⁴⁸. In contrast to homopolymers the phase transition of copolymers is very broad. Indeed, the copolymers with disproportionate stoichiometry reveal three Tg which correspond to the Tg of each homopolymers and Tg corresponding to the miscible phase. Whereas, in the case of the copolymer P3 (feed ratios of (5) = (6) = 50%) a single Tg was observed, and their value is higher than of their corresponding parent homopolymers P1 and P5. When the stoichiometry is equivalent, the copolymer presents a single Tg greater than that of the homopolymers, When (5) and (6) are stoichiometrically equivalent (Ratio=1), the copolymer presents a single Tg greater than that of the homopolymers which can probably be explained by a better interaction between the molecular chains for the homopolymers.

The thermal stability of the obtained polyimides was assessed using thermogravimetric analyses (TGA), and the temperatures of 5% weight loss ($T_{d5\%}$) of these polymers are listed in Table 1 and thermograms in Figure S2. As observed in Table 1, the homopolyimide based on partially bio-based anhydride (5) shows rather lower stability ($T_{d5\%}=451$ °C). Furthermore, we observed that thermal stability decreases as the portion of ISDA (isosorbide moieties (5)) increased. Despite this, all the synthesized polyimides are highly thermostable, with a starting decomposition temperature between 451 - 500°C (for homopolyimides based on 6FDA, $T_{d5\%}>500$ °C), which indicated that the incorporation of bio-based isosorbide moieties into homopolyimide or copolyimide backbones was not noticeably detrimental to the thermal stability of the resulting polyimides.

3.2. Study of the polyimide/electrolyte interface in presence of WFD heavy metal ions by EIS Measurements

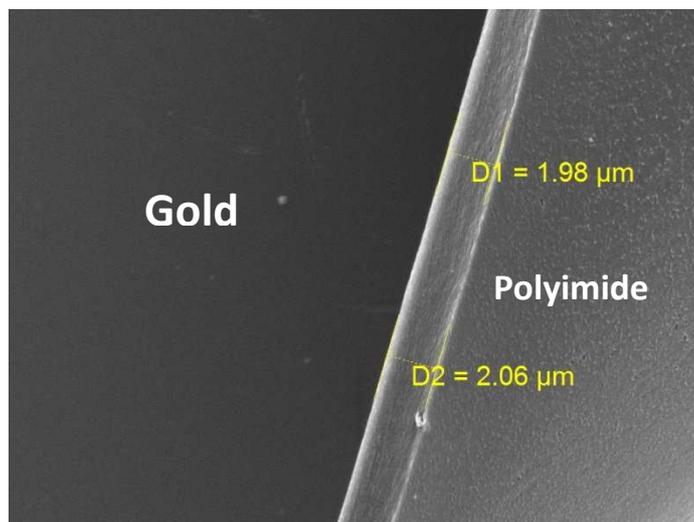

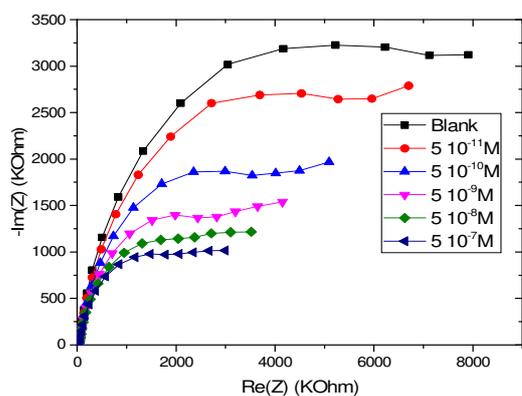

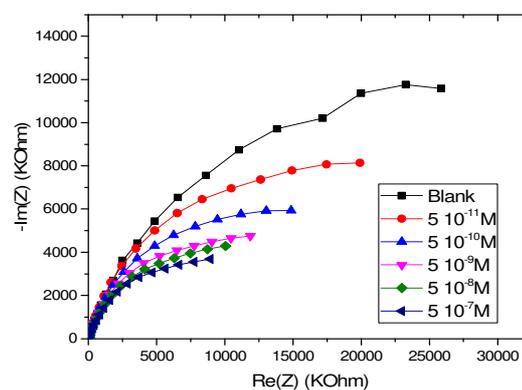

Figure 3. SEM image of a polyimide film deposited on gold surface.

The thickness of polyimide films on gold surface was determined by SEM (Figure 3). The average thickness of the polyimide films is $2.0 \pm 0.2 \mu\text{m}$.

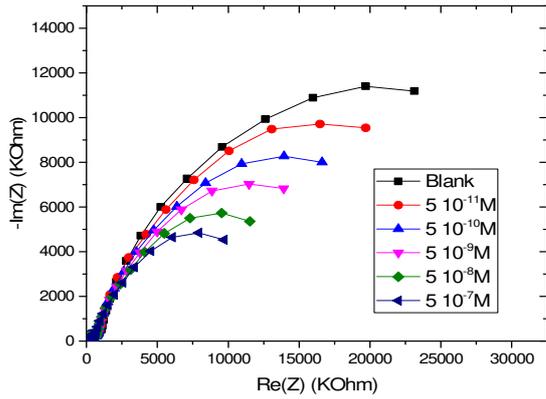

Nyquist diagrams of the gold electrode/polyimide/electrolyte obtained in presence of Pb^{2+} ion are presented in Figures 4 (a,b,c,d,e).

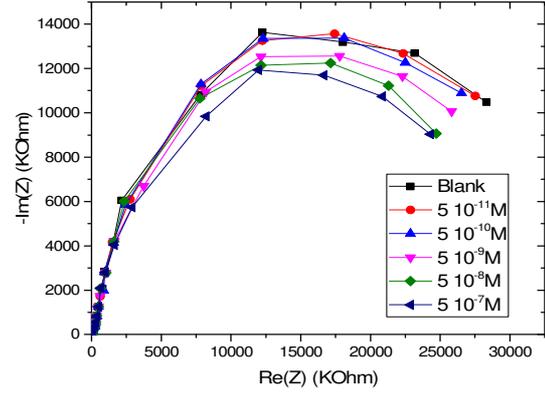

(a)

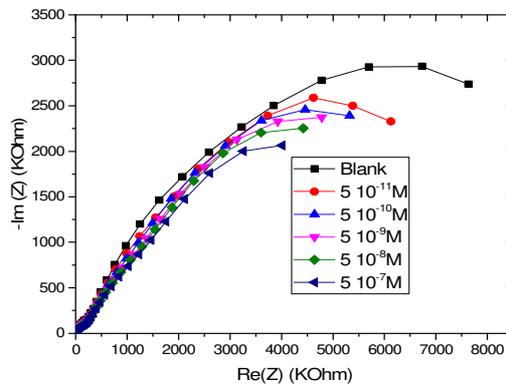

(b)

(c)

(d)

(e)

Figure 4. Nyquist plots of the gold electrode/polyimide/electrolyte obtained in presence of Pb^{2+} ion. Measuring solution: 0.1 M potassium citrate solution at pH 4.0

From the values of the imaginary part of the impedances of the homopolyimides (lower than 3500 kOhms) are lower than those of the copolyimides (in the range of 10^4 kOhms). From this observation, it comes that the capacitance of the homopolyimides are higher, which is due to their higher dielectric constant. This point reflects their higher density due to a better interaction between the molecular chains for the homopolymers.

The main parameter of the standard Randles equivalent circuit affected when the concentration of Pb^{2+} increases, is the polarization resistance, as shown in Table 2.

Table 2. Variation of the polarization resistance in the Randles standard equivalent circuit when the concentration of Pb²⁺ increases

[Pb]	P1 (Rp (Ohm))	P2 (Rp (Ohm))	P3 (Rp (Ohm))	P4 (Rp (Ohm))	P5 (Rp (Ohm))

5 10 ⁻¹¹ M	1.2360 10 ⁷	2.1149 10 ⁶	2.9656 10 ⁷	3.8230 10 ⁷	9.8955 10 ⁶
5 10 ⁻¹⁰ M	8.4203 10 ⁶	1.8289 10 ⁶	2.5588 10 ⁷	3.7485 10 ⁷	9.4415 10 ⁶
5 10 ⁻⁹ M	6.4453 10 ⁶	1.4974 10 ⁶	2.2213 10 ⁷	3.5283 10 ⁷	8.4189 10 ⁶
5 10 ⁻⁸ M	5.4007 10 ⁶	1.3669 10 ⁶	1.7558 10 ⁷	3.3910 10 ⁷	7.9800 10 ⁶
5 10 ⁻⁷ M	4.7701 10 ⁶	1.1211 10 ⁶	1.4851 10 ⁷	3.2425 10 ⁷	6.9090 10 ⁶

The relative variation of the polarization resistance is proportional to the adsorbed concentration q_e of Pb²⁺ at the polyimide surface. The adsorption isotherm of Pb²⁺ was then built from this value. The initial concentration of Pb²⁺ was not highly modified, due to the small surface area of the polymer in contact. Two models were tested: Langmuir and Freundlich. The Langmuir model assumes that adsorption occurs on a structurally homogeneous adsorbent in a monolayer, or that the adsorption occurs at fixed sites that are identical and energetically equivalent. The linearized form of the Langmuir isotherm can be written as follows:

$$c_e/q_e = 1/Q_0b + c_e/Q_0$$

where c_e is the concentration in solution and q_e , the adsorbed concentration, Q_0 is the adsorption capacity and b is the energy of adsorption (M^{-1}). Due to our assessment of q_e , the obtained value of Q_0 is a relative value.

Freundlich isotherm is another form of the Langmuir model describing a heterogeneous system with multiple adsorption sites. The linearized logarithmic form of the Freundlich model can be expressed as follows:

$$\log q_e = \log K_F + (1/n) \log c_e$$

where K_F is the relative value of the Freundlich constant and n is the Freundlich exponent.

The modelling parameters are given in Tables 3a and 3b.

Table 3a. Parameters of Langmuir model of Pb^{2+} adsorption isotherms on the different polyimides.

Polymer	R^2	Q_0	$b (M^{-1})$
P1	0.9998	0.726	2.177×10^{-9}
P2	0.9999	0.641	1.281×10^{-9}
P3	0.9997	0.605	2.418×10^{-9}
P4	0.9992	0.165	4.942×10^{-9}
P5	0.9992	0.262	7.847×10^{-9}

Table 3b. Parameters of Freundlich model of Pb^{2+} adsorption isotherm on the different polyimides.

Polymer	R^2	$1/n$	K_F
P1	0.959	0.096	3.120
P2	0.945	0.079	2.156
P3	0.978	0.063	1.513
P4	0.925	0.308	19.957
P5	0.874	0.422	200.955

Considering the R^2 value, the Langmuir model fits perfectly Pb^{2+} adsorption isotherm. The higher value of Q_0 is obtained with polymer P1. Value of $1/n$ for all the polymers being less than 1, it means that the adsorption process is favorable for all the polymers. The adsorption on polyimides containing isosorbicid moieties (5) is more favorable for Pb^{2+} adsorption. This property could be due to the hydrophilicity of these moieties.

The adsorption isotherms of all the WFD heavy metals on polymer P1 were fitted according to the Langmuir and Freundlich models (Tables 4a and 4b).

Table 4a. Parameters of the Langmuir model of WFD heavy metals on polymer P1.

Heavy metal ion	R^2	Q_0	$b (L/mg)$
Pb	0.9998	0.726	2.177×10^{-9}
Ni	0.9999	0.818	1.636×10^{-9}
Cd	0.9998	0.488	2.444×10^{-9}
Hg	0.9998	0.084	2.506×10^{-9}

Table 4b. Parameters of the Freundlich model of WFD heavy metals on polymer P1.

Heavy metal ion	R^2	$1/n$	K_F
Pb	0.959	0.096	3.120
Ni	0.969	0.064	2.157

Cd	0.963	0.102	2.301
Hg	0.908	0.181	1.420

For all the WFD heavy metals, the Langmuir model gives the best fitting. The higher value of Q_0 is obtained for Ni^{2+} and Pb^{2+} . According to $1/n$ values, adsorption of Ni^{2+} and of Pb^{2+} are more favorable. The adsorption of Hg^{2+} is the less favorable. These results are within the paradigm of Pearson's HSAB principle, wherein borderline cations Pb^{2+} and Ni^{2+} are expected to interact more strongly with the hard anion (O^-) and, consequently, soft cations (Cd^{2+} and Hg^{2+}) interact the least⁴⁹. A complex configuration is proposed in Figure 5, as a similar conformation as that proposed for xanthone-based polyimides⁴².

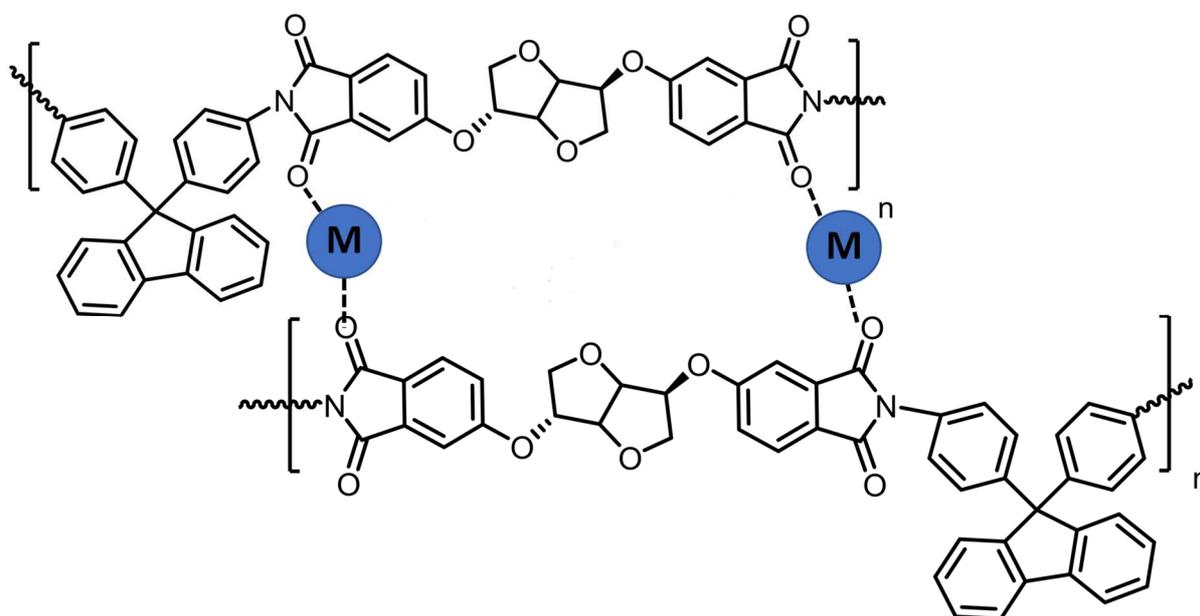

Figure 5. Metal-polyimide complex based on oxygen-heavy metal interaction.

The relative variation of the polarization resistance ($\Delta R/R$) is the response of the P1 modified gold electrode for the detection of WFD heavy metal ions. The sensitivity of detection (S) is defined as the slope of the straight line of $\Delta R/R$ versus log of metal concentration. The analytical performance of this heavy metal sensor is presented in Table 5, LOD being the Limit of Detection, determined as $3\sigma/S$, σ being the background of the blank.

Table 5. Analytical performance of the isosorbide based polyimide (P1) modified gold electrode with impedance measurements (Sensitivity, detection limit, linear range) compared to those obtained with anodic stripping voltammetry (ASV) on a boron-doped diamond electrode (BDD) and those of a potentiometric sensor.

Heavy Metal Ion	Electrochemical Methods	Sensitivity	LOD [M]	Linear range [M]
Pb ²⁺	Impedancemetry	0.111/decade	5x10 ⁻¹¹	5x10 ⁻¹¹ – 5x10 ⁻⁷
	ASV	0.069 nA/nM	5.5x10 ⁻⁹	5.5x10 ⁻⁹ – 48x10 ⁻⁹
	Potentiometry	29.7 mV/decade	4x10 ⁻⁹	1x10 ⁻⁸ – 1x10 ⁻⁴
Ni ²⁺	Impedancemetry	0.087/decade	5x10 ⁻¹¹	5x10 ⁻¹¹ – 5x10 ⁻⁷
	ASV	0.024 nA/mM	6.8x10 ⁻⁹	6.8x10 ⁻⁹ – 97x10 ⁻⁹
Cd ²⁺	Impedancemetry	0.073/decade	5x10 ⁻¹¹	5x10 ⁻¹¹ – 5x10 ⁻⁷
	ASV	0.015 nA/nM	0.4x10 ⁻⁹	0.4x10 ⁻⁹ – 35x10 ⁻⁹
Hg ²⁺	Impedancemetry	0.018/decade	5x10 ⁻¹¹	5x10 ⁻¹¹ – 5x10 ⁻⁷
	ASV	0.012 nA/nM	2.3x10 ⁻⁹	2.3x10 ⁻⁹ – 5x10 ⁻⁹

For P1, with impedance measurements, the higher sensitivity is obtained for Pb²⁺ and the lower for Hg²⁺. The detection limit obtained with P1 for is 50 pM for all the WFD heavy metals. This detection limit of Pb²⁺ is 110 times lower than that obtained by anodic stripping voltammetry on boron-doped diamond electrode (BDD), 5.5 nM [50] and that obtained by potentiometry, 4 nM [51]. Its dynamic range is four decades which is larger than that obtained with ASV (one decade) and equal to that of potentiometry (four decades). Comparing the detection limit of the other WFD heavy metals obtained with ASV to those obtained with P1 and impedance measurements, it is 136 times higher for Ni²⁺, 8 times higher for Cd²⁺ and 46 times higher for Hg²⁺.

4. Conclusions

The novelty of this work consists on the synthesis and characterization of new biosourced polyimides derived from unprecedented combinations of monomers (Isosorbide, 6-FDA and amine cardo), to introduce new properties. The characterization of the resulting polymers was obtained by NMR spectroscopy, SEC, TMA, TGA and AFM. All polymers have a high thermal stability with 5% weight loss above 451 °C in nitrogen atmosphere. Metal ion adsorption capacities of polymers were measured on the polyimide modified gold electrode interface by EIS. The obtained results showed that the incorporation of the dianhydride based on isosorbide (5) to the main chain enhance the adsorption capacity of lead ion. The equilibrium adsorption data of all polymers were found to adopt the Langmuir isotherm model. Regarding the adsorption capacities of the different WFD heavy metals on the isosorbide based homopolyimide (P1), the sequence was as follows: Pb²⁺ ≈ Ni²⁺ > Cd²⁺ > Hg²⁺. The developed bio-based polyimide modified sensor displayed a good sensitivity with a detection limit up to 50 pM for all the WFD heavy metals which can prove its potential for the control of drinkable

water contamination. Moreover, due to its affinity for WFD heavy metals, the isosorbide-based polyimide is a potential candidate for their removal from effluents.
