55 **Introductory paragraph**

56 The ability of gut bacterial pathogens to escape immunity by antigenic variation,
57 particularly via changes to surface-exposed antigens, is a major barrier to
58 immune clearance¹. However, not all variants are equally fit in all
59 environments^{2,3}. It should therefore be possible to exploit such immune escape
60 mechanisms to direct an evolutionary trade-off. Here we demonstrated this
61 phenomenon using *Salmonella enterica* subspecies *enterica* serovar
62 Typhimurium (S.Tm). A dominant surface antigen of S.Tm is its O-antigen: A
63 long, repetitive glycan that can be rapidly varied by mutations in biosynthetic
64 pathways or by phase-variation^{4,5}. We quantified the selective advantage of O-
65 antigen variants in the presence and absence of O-antigen specific IgA and
66 identified a set of evolutionary trajectories allowing immune escape without an
67 associated fitness cost in naïve mice. Through the use of oral vaccines, we
68 rationally induced IgA responses blocking all of these trajectories, which
69 selected for *Salmonella* mutants carrying deletions of the O-antigen
70 polymerase *wzyB*. Due to their short O-antigen, these evolved mutants were
71 more susceptible to environmental stressors (detergents, complement),
72 predation (bacteriophages), and were impaired in gut colonization and
73 virulence in mice. Therefore, a rationally induced cocktail of intestinal antibodies
74 can direct an evolutionary trade-off in S.Tm. This lays the foundations for the
75 exploration of mucosal vaccines capable of setting evolutionary traps as a
76 prophylactic strategy.

77

78 **Main text**

79 The gut is a challenging environment for bacteria with high densities of phage,
80 bile acids, antimicrobial peptides and secretory antibodies. These interact first
81 with the outermost layer of the bacterial surface. Long, repetitive glycans, such
82 as capsular polysaccharide, teichoic acids or O-antigens are ubiquitous as the
83 outermost defense in bacteria. A particularly relevant feature of these glycan
84 structures is that small changes in the structure of the repeating units, such as
85 gain or loss of acetyl groups, when polymerized, result in major changes in
86 conformation and charge-distribution of the glycans.

87 In the case of non-Typhoidal *Salmonella* this outermost glycan layer is
88 predominantly made up of O-antigen: lipopolysaccharide core-linked, long,
89 repetitive heteroglycans that hide most common outer-membrane proteins ^{(6,7,}
90 **Fig.ED1**). The *S.Tm* wild type (*S.Tm*^{WT}) O:4[5], 12-0 O-antigen is a polymer of
91 a triose repeating backbone (-mannose- α -(1 \rightarrow 4)-rhamnose- α -(1 \rightarrow 3)-
92 galactose- α -(1 \rightarrow 2), constituting the O:12-0 epitope) with an α -(1 \rightarrow 3)-abequose
93 side-branch at the mannose (constituting the O:4 epitope, or when O-acetylated
94 the O:5 epitope) (**Fig. 1A**). The *S.Tm*^{WT} reacts to O:5-typing antisera and O:12-
95 0-typing antibodies (**Fig. 1B, and C, S1-3**). In the SL1344 strain of *S.Tm*, two
96 major shifts in O-antigen composition have been reported. Firstly, complete loss
97 of abequose acetylation, generating an O:4-only phenotype, occurs via loss of
98 function mutations in the abequose acetyl transferase gene *oafA*⁸, (**Fig. 1A and**
99 **B**). Secondly, the O:12-0 epitope can be converted to an O:12-2 epitope by (α -
100 (1 \rightarrow 4) glucosylation of the backbone galactose (**Fig. 1A and C**). This occurs
101 via expression of a glucosyl transferase *gtrABC* operon (STM0557-0559),
102 controlled by DAM-dependent methylation i.e. by phase variation^{4,9}. Note that
103 *S.Tm* strain SL1344 lacks a second common operon required for linking

104 glucose via an α -(1→6) linkage to the backbone galactose, generating the O:1
105 serotype. All of these structural O-antigen variants exert only a mild fitness
106 defect in the naïve gut (^{5,9,10}, **Fig 1D and E**). However, there is also evidence
107 for selection of mutants at loci coding for the O-antigen polymerases and so-
108 called “non-typable” *Salmonella* strains with a single-repeat O-antigen are
109 occasionally observed amongst isolates from infected humans or animals¹¹.
110 Such strains lose outer membrane robustness, due to loss of the rigid
111 hydrophilic glycan layer¹², . and therefore have decreased fitness both in the
112 gut and in the environment^{2,3,13}.
113 We hypothesized that the host's immune response could generate conditions
114 in which the fitness of O-antigen polymerase mutants is promoted, driving the
115 emergence of an evolutionary trade-off. Intestinal antibodies (predominantly
116 secretory IgA) are known to exert specific selective pressures on targeted
117 species^{14–16}. In order to investigate the evolutionary consequences of vaccine-
118 induced secretory antibody responses in the gut, without the major ecological
119 shifts associated with live-attenuated vaccine infection^{17–19}, we made use of an
120 established high dose, inactivated oral vaccination technique^{15,20,21} that induces
121 intestinal IgA responses without detectable intestinal damage, inflammation or
122 colonization by the vaccine strains²¹. Our standard vaccine (“PA-S.Tm”)
123 consists of concentrated peracetic acid killed bacteria²¹. Conventional mice
124 harboring a complex microbiota (16S amplicon analysis available²²) received
125 10^{10} particles of PA-S.Tm orally once per week for 4 weeks. Subsequently,
126 these mice were antibiotic-treated to open a niche for the pathogen in the large
127 intestine, and were infected with S.Tm SL1344, which rapidly colonizes the

128 cecum, generating typhlocolitis, and invasive disease in the mesenteric lymph
129 nodes, spleen and liver^{23,24}.

130 We first quantified the competitive fitness of *S.Tm* mutants genetically “locked”
131 into individual structural O-antigen compositions in vaccinated and naïve mice.
132 Competition between *S.Tm* ^{Δ oafA Δ gtrC} (**O:4**, O:12-0-locked) and *S.Tm* ^{Δ gtrC}
133 (**O:4[5]**, O:12-0-locked) demonstrated no difference in fitness in naïve mice
134 over 4 days of infection. However, in mice vaccinated either against the O:4 or
135 the O:4[5] variant (**Fig. S4**), we observed up to a 10⁷-fold outcompetition of the
136 IgA-targeted O-antigen variant within 4 days (**Fig. 1D**). The magnitude of the
137 selective advantage correlated with the magnitude of the intestinal IgA
138 response to each O-antigen variant (**Fig. 1F and G**). Therefore, IgA can exert
139 a strong selective pressure on the O:4/O:4[5] O-antigen variants. Competing
140 *S.Tm* ^{Δ oafA} (**O:12-phase-variable**, O:4) against *S.Tm* ^{Δ oafA Δ gtrC} (**O:12-locked**,
141 O:4) revealed a mild benefit of O:12 phase variation in naïve mice up to day 4
142 post-infection, in line with published data (**Fig. 1E**)^{4,5}. However, we observe a
143 major fitness benefit of phase variation in vaccinated mice in which the IgA
144 response is highly biased to recognition of O:12-0 O-antigens (**Fig. 1E, H**. Red
145 symbols, **Fig. S5**). Correspondingly, vaccinated mice with an outgrowth of
146 phase-variable *S.Tm* also displayed initiation of intestinal inflammation, as
147 quantified by fecal Lipocalin 2 (LCN2, **Fig. 1I**). The mechanistic basis of this
148 selective advantage could be confirmed by complementation of the *gtrC* gene
149 in trans (**Fig. S6**). Therefore O:12-0-targeting IgA can exert a strong selective
150 pressure against *S.Tm* unable to phase-vary the O:12-0 part of the O-antigen.
151 As neither of these variants (O:4[5] to O:4 and O:12-0 to O:12-2) are associated
152 with a major loss-of-fitness in naïve mice (**Fig. 1D and E**), this implied that such

153 variants should be selected for during infections of vaccinated mice with wild
154 type *Salmonella*.

155 We therefore established whether natural emergence of these “IgA-escape”-
156 S.Tm variants occurred sufficiently fast to be observed during wild type S.Tm
157 infections. For this purpose, we treated mice with a wild type PA-S.Tm oral
158 vaccine as above, or with a vehicle-only control, and then challenged these
159 animals with wild type S.Tm. Around 30% of vaccinated mice showed intestinal
160 inflammation at 18 h post infection (**Fig. 2A**), despite the presence of robust
161 anti-S.Tm^{wt} intestinal IgA in all vaccinated animals (**Fig. 2B**). When S.Tm
162 clones were recovered from the cecal content of vaccinated mice with intestinal
163 inflammation, these were typically recognized less well by vaccine-induced IgA
164 than S.Tm clones from the cecum of vaccinated and protected mice (**Fig. 2C**).
165 In 11 of 34 mice analysed, we observed clones with complete loss-of-binding
166 to an O:5-specific polyclonal antisera within 4 days (Table S3, **Fig 2D**).
167 Resequencing of O:5-negative clones confirmed a 7 bp contraction of a tandem
168 repeat in the open reading frame of *oafA*, coding for the abequose acetylase
169 (**Fig. 2E**, 10 different clones from three independent experiments), that is also
170 found in multiple NCBI deposited genomes²⁵ (**Fig. ED2A**). A second site of
171 microsatellite instability is present in the promoter of *oafA* suggesting a further
172 possibility for rapid inactivation (**Fig. ED2B**), and this gene was found to be
173 under negative selection in a recent screen of published *Salmonella*
174 genomes²⁶.

175 In contrast, loss of O:12-0 staining was bimodal within individual clones (**Fig.**
176 **2F**), consistent with phase-variation⁴ and no reproducible mutations were
177 identified in these clones on genome resequencing (**Table S3**). Instead,

178 methylation analysis revealed a methylation pattern indicative of the *gtrABC*
179 promoter being in an “ON” conformation (**Fig. 2G**). Serial passage of these
180 clones (**Fig. ED3A**), as well as cultivation in microfluidic devices
181 (**Supplementary videos 1 and 2**) confirmed the ability of clones to switch
182 between O:12-0-positive and negative states. The STM0557-0559 *gtrABC*
183 locus was confirmed to be essential for this observed loss of O:12-0 epitope as
184 strains lacking *gtrC* remained 100% O:12-0-positive even under strong *in vivo*
185 selection (**Fig. ED3B and C**). This phenotype could be replicated by adoptive
186 transfer of a recombinant monoclonal IgA specific for the O:12-0 epitope
187 (mSTA121, **Fig. ED4**), confirming that O:12-0-binding IgA is sufficient to drive
188 outgrowth of O:12-2-producing variants. Computational modeling of phase-
189 variation and growth, as well as comparison of O:12-0/O12:2 switching rates of
190 *lacZ* reporter strains suggested that selection for clones expressing *gtrABC* is
191 sufficient to explain the recovery rate, without any intrinsic shift in phase
192 variation switching rates (**Fig. ED5**). The chemical structure of O-antigen of the
193 recovered clones was further confirmed by ¹H-NMR of purified O-antigen and
194 by high resolution magic-angle spinning NMR of O-antigen on the surface of
195 intact cells (**Fig. ED6**). Therefore, vaccine-induced IgA can select for the natural
196 emergence of O-antigen variants within a few days of infection with *S.Tm* wild
197 type, resulting in disease in vaccinated mice. This phenomenon can also be
198 observed at later time-points in IgA-competent but not IgA-deficient mice during
199 chronic infection with live-attenuated *S.Tm* strains (**Fig. ED7A and B**) i.e. IgA
200 is necessary for selection of O-antigen variants during chronic infection.
201 Correspondingly, although the inactivated oral vaccines induce a higher titre of
202 *Salmonella*-binding IgA than the live vaccines (**Fig. ED7C**), the response to

203 chronic infection binds to O:4 and O4[5]-producing *S.Tm* with similar titres,
204 while the response to inactivated vaccine is highly biased for the O-antigen
205 variant of the vaccine (**Fig. ED7C**). This indicates that within-host O-antigen
206 variation also occurs under the selective pressure of intestinal antibodies during
207 chronic infections, and sequential priming will include a broad IgA response
208 capable of recognizing multiple O-antigen variants.

209

210 We next investigated whether the relative fitness defect of a short O-antigen
211 mutant can be compensated for by the selective advantage from lower IgA-
212 binding in the gut lumen, i.e. whether IgA could drive an evolutionary trade-off.
213 One-on-one competitions were carried out between *S.Tm* ^{Δ oafA Δ gtrC} (O:4,12-0-
214 locked, **long O-antigen**) and *S.Tm* ^{Δ oafA Δ gtrC Δ wzyB} (O:4,12-0-locked, **short O-**
215 **antigen**, retains just a single O-antigen repeat) in the intestine of mice with and
216 without IgA raised against *S.Tm* ^{Δ oafA Δ gtrC} (**Fig. 3A**). The single repeat O-antigen
217 strain was rapidly outcompeted in naive animals, in line with earlier studies^{11,27}
218 (**Fig. 3A**) indicating a major loss-of-fitness. However, in the gut of vaccinated
219 mice, strains with short O-antigen were dominant by day 4 (**Fig. 3A**).
220 Vaccinated antibody-deficient mice were indistinguishable from naive mice in
221 these experiments, verifying that IgA is necessary for the selection of short O-
222 antigen strains in the gut of vaccinated mice (**Fig. 3A**). Introduction of day 4
223 fecal bacteria from vaccinated mice into naïve mice resulted in re-outgrowth of
224 the strain with a long O-antigen, indicating that vaccine-induced IgA, and not
225 secondary mutations in *S.Tm* ^{Δ oafA Δ gtrC Δ wzyB}, was responsible for competition
226 outcome (**Fig. 3B**). The IgA titre recognizing short O-antigen-producing strains
227 was lower than that against full-length O-antigen strains, consistent with the

228 selective advantage in vaccinated mice (**Fig. 3C**). As the long O-antigen can
229 have several hundred repeats of the glycan, decreased antibody binding could
230 be driven by lower O-antigen abundance or by loss of avidity-driven
231 interactions. Loss of long O-antigen can therefore be an advantage to
232 *Salmonella* in the gut lumen of vaccinated mice.

233 Based on these above observations, we hypothesized that emergence of
234 mutants with a short O-antigen could be achieved for a wild type S.Tm infection
235 if we could block all other IgA escape routes, effectively generating an
236 evolutionary trap. To this end, mice received an oligovalent vaccine containing
237 the **O:4[5],12** S.Tm ^{Δ gtrC}, **O:4,12** S.Tm ^{Δ oafA Δ gtrC}, **O:4,12-2** S.Tm ^{Δ oafA} pgtrABC,
238 and **O:4[5],12-2** S.Tm pgtrABC strains (referred to as PA-S.Tm^{ET}). This
239 induced a broad antibody response with high avidity for all four of the known
240 long O-antigen variants present in our S.Tm SL1344 strain (**Fig. 3D, Fig.S7-8**).
241 PA-S.Tm^{ET} provided subtly better protection from intestinal inflammation in
242 long-term infection of 129S1/SvImJ mice than the monovalent **O:5,12-0** vaccine
243 (**Fig. 3E**, significant protection from intestinal inflammation at d9 with
244 PA-S.Tm^{ET} but not PA-S.Tm ^{Δ gtrC}), as well as on mixed challenge of Balb/c mice
245 (**Fig. S9**, significant protection from intestinal inflammation at d4 with
246 PA-S.Tm^{ET} but not PA-S.Tm ^{Δ gtrC}). Moreover, our hypothesis that this vaccine
247 can set an evolutionary trap was supported: short O-antigen-producing clones
248 were detected in 12 of 18 PA-S.Tm^{ET} vaccinated mice analysed across multiple
249 experiments by phenotypic characterization (anti-O5^{dim} flow cytometry staining,
250 **Fig. 3F**). The O-antigen phenotype was confirmed by gel electrophoresis of
251 purified LPS (**Fig. 3G**). Sequencing of evolved short-O-antigen clones (**Table**
252 **S4**, n=5) revealed a common large deletion encompassing the *wzyB* gene (also

253 termed *rfc*), encoding the O-antigen polymerase¹¹ (**Fig. 3H**, **Fig. ED8** also
254 reported in some "non-typable" *S.Tm* isolates from broilers¹¹). This deletion is
255 mediated by site-specific recombination between flanking direct repeats, which
256 renders the *wzyB* locus unstable¹¹.

257 We have previously published that IgA responses against the surface of rough
258 *Salmonella* are identically induced by vaccination with either rough or wild type
259 *Salmonella* oral vaccines²⁸. Correspondingly, including a short-O-antigen
260 mutant into our PA-*S.Tm*^{ET} mix does not further improve IgA titres (**Fig. S10**).
261 Note that in these experiments, we also do not observe a significant
262 improvement of protection with PA-*S.Tm*^{ET}, as PA-*STm*^{WT} protected well out to
263 day 3 in n=6 of 8 mice, when the experiment was terminated for ethical reasons
264 relating to the control group. As the generation of *Salmonella* O-antigen variants
265 is inherently stochastic, but a prerequisite for selection by IgA and therefore
266 within-host evolution, perfect protection can be observed in a variable fraction
267 of animals that had received the monovalent vaccine up to this time-point.
268 However, no intestinal inflammation, as quantified by fecal Lipocalin-2, was
269 observed in any of the mice receiving PA-*S.Tm*^{ET} (n=9) or PA-*S.Tm*^{ET+wzyB}
270 (n=4).

271 We finally confirmed that re-isolated *wzyB*-deletion mutants phenocopied the
272 fitness defects of targeted *wzyB* mutations in harsh environments. Single
273 infections with *S.Tm* ^{Δ oafA Δ grC Δ wzyB} revealed that, in comparison to isogenic wild
274 type counterparts, *wzyB*-deficient mutants (synthetic or evolved) are
275 significantly less efficient at colonizing the gut of streptomycin pretreated naïve
276 mice (**Fig. 4A**), disseminating systemically (**Fig. 4B**) and triggering
277 inflammation (**Fig. 4C**), i.e. they have an intrinsic defect in colonization and

278 virulence. This attenuation can be attributed to compromised outer membrane
279 integrity¹² and also manifests as an increased sensitivity to membrane
280 destabilization by EDTA, bile acids and weak detergents (**Fig ED9A-E**) and
281 increased sensitivity to complement-mediated lysis^{11,27} (**Fig. ED9F**). It is also
282 well-documented that specific interactions between the tail spike fiber and O-
283 antigen reduce the host-range of ubiquitous lytic phages^{29,30}. Correspondingly,
284 infection of the short-O-antigen strains with filtered wastewater generated
285 visible lysis plaques of various sizes (**Fig. 4D and E, Fig. ED10A**). About 10-
286 fold less lysis plaques were visible in the same conditions with long O-antigen
287 strains (**Fig. 4D and E, Fig. ED10A**). Sequencing of phages isolated from four
288 plaques revealed four different T5-like phages (**Fig. 4F**). Infections with the
289 purified phage $\phi 12$ yielded more phages after infection of a short O-antigen
290 evolved clone compared to the ancestor strains (**Fig. 4G**). We could confirm
291 that infection was dependent on *btuB*, the vitamin B12 outer-membrane
292 transporter that is normally shielded by a long O-antigen (**Fig, ED10B and**
293 **C**). These results confirmed that the recovered *wzyB* mutants were indeed
294 sensitive to diverse membrane stresses, innate immune defenses and common
295 environmental phages that would be encountered during transmission or on
296 infection of a new host. Therefore, vaccination can successfully drive evolution
297 toward fitness trade-off *in vivo*.

298 These observations revealed the overlap between host IgA driven- and phage-
299 driven *Salmonella* evolution. Both the *oafA* gene and the *gtrABC* operon are
300 found at bacteriophage remnant loci, indicating that *S.Tm* has co-opted
301 functions modulating sensitivity to bacteriophage attack in order to escape
302 adaptive immunity. Of note, this example of “coincidental evolution”^{31,32} could

303 be also driven by and influence how *Salmonella* escape protozoa predator
304 grazing in the gut³³. As protozoa are specifically excluded from our SPF mouse
305 colonies, this effect could not be investigated here.

306 Our data, along with previous work on O:4[5] and O:12 variation^{4,5,9,10}, clearly
307 indicated direct selective pressure of the host immune system for within-host
308 evolution/phase variation of the O-antigen. Nevertheless, IgA specificity is only
309 one of many strong selective pressures that can be present in the intestine of
310 a free-living animal. Previous work^{20,32-34} indicates that inflammation, phage
311 and predation by protozoa can all contribute, and may exhibit complex
312 interactions. For example, inflammation induces the lytic cycle of a temperate
313 phage: a phenomenon inhibited by IgA-mediated protection from disease²⁰.
314 Inflammation is also expected to be particularly detrimental to O-antigen-
315 deficient strains that are poorly resistant to antimicrobial peptides and bile
316 acids³ (Fig. ED9). Aggregation of *Salmonella* by IgA may also generate
317 particles that are too large for protozoal grazing, further interacting with
318 bacterial predation in the gut, although this hypothesis has not been
319 experimentally tested. We hope that our work has generated a framework and
320 a set of tools that can be applied to better understand the influence of intestinal
321 adaptive immunity on within-host evolution of bacteria more comprehensively,
322 and that eventually this can be translated into better control of enteric
323 pathogens. In our case, we observed that a tailored adaptive immune response
324 can influence the evolution of bacteriophage/bacteria interactions to the
325 detriment of the bacteria.

326 We have focused on one particular *S.Tm* strain here and it remains to be seen
327 how far this concept can be extended. Further phage-encoded modification of

328 the O-antigen, such as the O:12-1 modification⁴ will likely be required to make
329 robust “evolutionary traps” for *Salmonella* Typhimurium “in the wild”.
330 Additionally, species capable of producing capsular polysaccharides that mask
331 the O-antigen, such as *Salmonella* Typhi and many *E.coli* strains, would require
332 additional vaccine components (typically glycoconjugates) able to induce
333 robust anti-capsule immunity. However, we expect the principle uncovered
334 here, i.e. understanding the rapid within-host evolution of bacterial surface
335 structures and using this information to rationally design oligomeric vaccines,
336 to be broadly applicable. Correspondingly, our findings are consistent with
337 earlier reports of IgA-mediated selection of surface glycans in diverse
338 species^{14,35}, and an earlier report that *gtrABC*-mediated O-antigen phase-
339 variation of *Salmonella* Typhimurium ATCC 14028 confers a colonization
340 benefit starting at day 10 post-infection (roughly the time when an IgA response
341 would be first detected)⁵. Surface variation of teichoic acids for immune evasion
342 can also be prophage-driven in *Staphylococcus aureus*³⁶, although adaption of
343 antibody-based techniques for gram-positive pathogens that are masters of
344 immune evasion will likely be beyond the limits of this approach.

345 “Evolutionary trapping” of *Salmonella* by vaccine-induced IgA does not require
346 any effect of IgA on the intrinsic mutation rate or phase-switching rates of
347 *Salmonella*. Rather within-host evolution is the product of specific selective
348 pressures (driven by IgA) on mutants and phase variants with changes in O-
349 antigen structure, which are spontaneously generated at relatively high
350 frequencies in the course of any intestinal infection. This genetic plasticity of
351 large populations of microbes has always been the “Achilles heel” of antibiotic³⁷,
352 phage³⁸ or CRISPR-based³⁹ treatments, leading to resistance and treatment

353 failure. In the complex ecological setting of the intestine, where bacterial
354 populations are large and relatively fast-growing, within-host evolution can be
355 rapid, and surprisingly predictable. Via rationally designed oral vaccines, we
356 demonstrate that this force can be harnessed to weaken pathogenicity and to
357 alter bacterial susceptibility to predation. We therefore propose that
358 understanding the most common within-host evolutionary trajectories of gut
359 pathogens holds the key to developing robust prophylactics and therapies.

554 Acknowledgements

555 OH acknowledges Heiko Käßner for recording NMR spectra, Regina Engel for
556 GLC-MS, and Katharina Jakob and Sylvia Düpow for technical support. We
557 want to thank Magdalena Schneider, Christine Kiessling, Elisabeth Schultheiss,
558 Rosa-Maria Vesco and Clarisse Straub for the DNA extraction, library
559 preparations and sequencing of the bacterial isolates. MD acknowledges
560 Delphine Cornillet and the group of Prof. Dirk Bumann for serum resistance
561 measurements.

562 ES, WDH and MD acknowledge Prof. Markus Aebi, Prof. Martin Loessner, Dr.
563 Joshua Cherry and the group of Dr. Alexander Harms for their helpful
564 discussion and insight, as well as members of the Hardt, Slack, and Diard
565 groups for their comments. They further acknowledge the staff of the ETH

566 Phenomics Centre and Rodent Centre HCI for support for animal
567 experimentation.

568

569 **Author contributions**

570 MD, WDH and ES designed the project and wrote the paper. MD and ES
571 designed and carried out experiments relating to vaccination and infection of
572 mice, re-isolation of S.Tm clones, phenotyping of S.Tm clones by flow
573 cytometry and gel electrophoresis, characterization of human monoclonal
574 antibodies, analysis of antibody titres, and analysis of fitness of O-antigen
575 variants of S.Tm *in vitro* and *in vivo*. MvdW, BHM, CL, RM contributed to
576 experimental design / data interpretation. GZ carried out HR-MAS NMR
577 analysis, OH carried out proton NMR analysis. MA generated the mathematical
578 model for O:12 switching. JA carried out and analysed all AFM imaging. AR,
579 NAB carried out phage-sensitivity assays. AE, FB, DW carried out Illumina
580 whole-genome resequencing of re-isolated S.Tm isolates. EB, VL, DH, FB,
581 KSM, SA carried out S.Tm challenge infections in vaccinated mice and
582 analysed re-isolated clones. AH carried out microfluidic video microscopy of
583 O:12 switching. PV and LF carried out methylome analysis of re-isolated S.Tm
584 clones. LP, AL and BMS generated novel antibody reagents. All authors
585 critically reviewed the manuscript.

586

587 **Funding**

588 MD is supported by a SNF professorship (PP00PP_176954) and Gebert Rüt
589 Microbials (PhagoVax GRS-093/20). ES acknowledges the support of the
590 Swiss National Science Foundation (40B2-0_180953, 310030_185128, NCCR

591 Microbiomes), European Research Council Consolidator Grant, and Gebert Rüt
592 Microbials (GR073_17). MD and ES acknowledge the Botnar Research Centre
593 for Child Health Multi-Investigator Project 2020. BMS acknowledges the
594 support of R01 AI041239/AI/NIAID NIH HHS/United States. WDH
595 acknowledges support by grants from the Swiss National Science Foundation
596 (SNF; 310030B-173338, 310030_192567, NCCR Microbiomes), the
597 Promedica Foundation, Chur, the Gebert Rüt Foundation (Displacing ESBL,
598 with AE) and the Helmut Horten Foundation. EB is supported by a Boehringer
599 Ingelheim Fonds PhD fellowship. BM acknowledges support by the Swiss
600 National Science Foundation (200020_159707).

601 **Competing Interests Statement**

602 M.D. W-D.H. and E.S. declare that Evolutionary Trap Vaccines are covered by
603 European patent application EP19177251. No other authors declare any
604 competing interests.

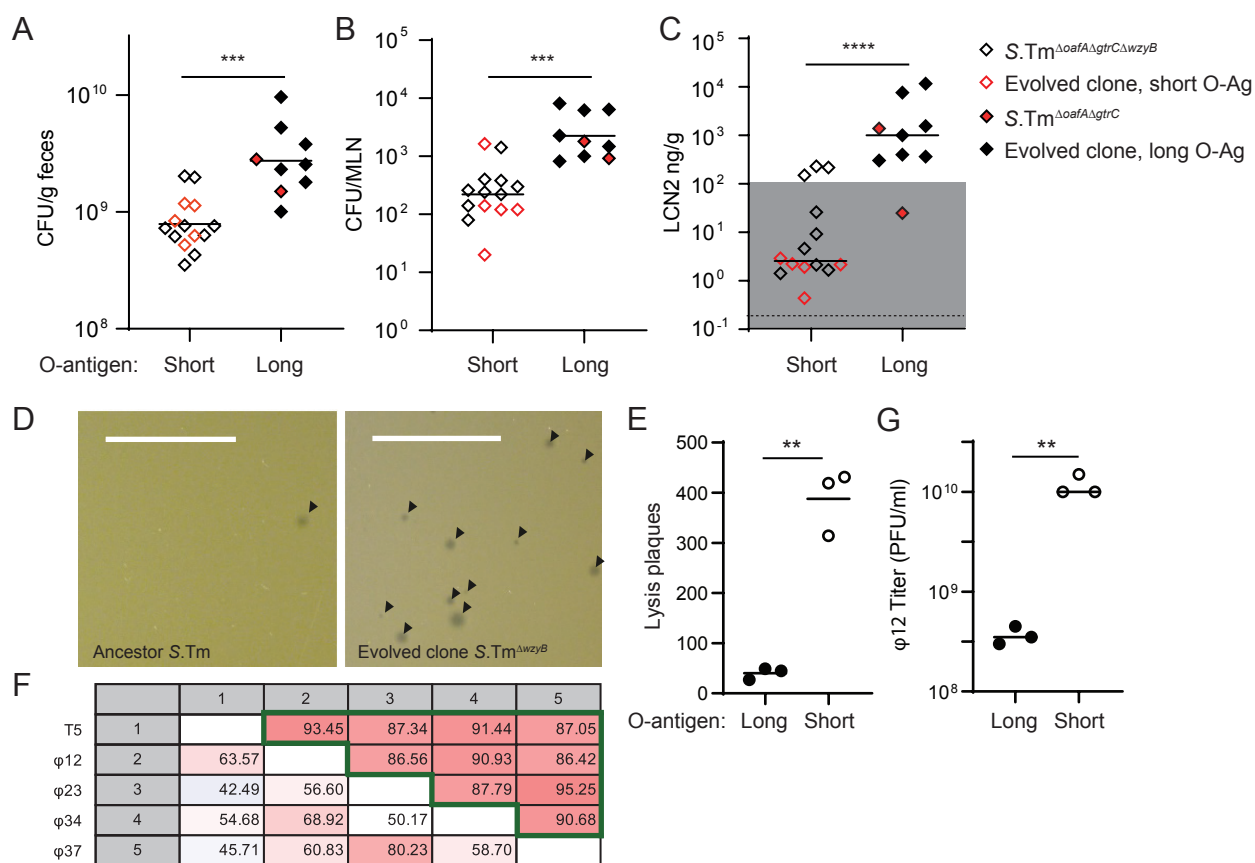

Figure 4: Single-repeat O-antigen mutants arising during infection of vaccinated mice have attenuated virulence, fitness and diminished resistance to phage predation

707 **Figure 4: Single-repeat O-antigen mutants arising during infection of**
708 **vaccinated mice have attenuated virulence, fitness and diminished**
709 **resistance to phage predation.**

710 **A, B, C**, Single 24h infections in streptomycin pretreated naïve C57BL/6 mice
711 (n=14, short O-antigen, n=9 long O-antigen). Evolved and synthetic *wzyB*
712 mutants have reduced ability to colonize the gut (**A**, CFU/g feces, ***p=0.0002)
713 and to spread systemically (**B**, CFU per mesenteric lymph node (MLN),
714 ***p=0.0001). This translates into diminished propensity to trigger intestinal
715 inflammation in comparison to isogenic wild type strains (**C**, fecal Lipocalin 2
716 (LCN2), ****p<0.0001). Mann-Whitney U, 2-tailed tests. **D**. Phage plaques on a
717 lawn of ancestor *S. Tm*^{wt} (left) and evolved *S. Tm*^{ΔwzyB} (right) after infection with
718 filtered wastewater; scale=1cm. **E**. Quantification of the plaques from three
719 independent experiments (2-tailed Paired T test **p=0.0046). **F**. Pairwise
720 comparison matrix of *de novo* assembled and aligned genomes of isolated
721 bacteriophages (φ12, φ23, φ34, φ37) and a reference sequence from
722 *Enterobacteriaceae* phage T5 (NC_005859). Values indicate the alignment
723 percentage (comparisons below diagonal) between genomes and the average
724 nucleotide identity between the aligned parts (comparisons above diagonal,
725 green frame). This analysis shows that the four isolated bacteriophages are
726 different but all belong to the T5 family. **G**. Quantification of phage plaques
727 formed on infection of the ancestor *S. Tm*^{wt} (long O-antigen) and evolved
728 *S. Tm*^{ΔwzyB} (short O-antigen) with the isolated phage φ12. 2-tailed Mann-
729 Whitney U test. **p=0.0041.
730

731 **Materials and Methods**

732 **Ethics statement**

733 All animal experiments were approved by the legal authorities (licenses 223/2010,
734 222/2013, 193/2016, 120/2019; Kantonales Veterinäramt Zürich, Switzerland). All
735 experiments involving animals were carried out strictly in accordance with the legal
736 framework and ethical guidelines.

737

738 **Mice**

739 Unless otherwise stated, all experiments used specific opportunistic pathogen-free
740 (SPF, containing a complete microbiota free of an extended list of opportunistic
741 pathogens) C57BL/6 mice. IgA^{-/-40}, Balb/c, JH^{-/-41}, Rag1^{-/-42} (all C57BL/6 background)
742 and 129S1/SvImJ, mice, were re-derived into a specific pathogen-free (SPF) foster
743 colony to normalize the microbiota and bred under full barrier conditions in
744 individually ventilated cages in the ETH Phenomics Center (EPIC, RCHCI), ETH
745 Zürich and were fed a standard chow diet. Low complex microbiota (LCM) mice
746 (IgA^{+/-} and ^{-/-}, used in Fig. ED2) are ex-germfree mice, which were colonized with a
747 naturally diversified Altered Schaedler flora in 2007¹⁴ and were bred in individually
748 ventilated cages or flexible-film isolators at this facility, and received identical diet. All
749 mouse facilities were regulated to maintain constant temperature (22°C +/- 1°C) and
750 humidity (30-50%), with a 12h/12h standard dark/light cycle. Male and female mice

751 were included in all experimental groups, and the number of animals per group is
752 indicated in each figure legend.

753

754 Vaccinations and chronic infections with attenuated *Salmonella* strains in naïve mice
755 were started between 5 and 6 weeks of age, and males and females were randomized
756 between groups to obtain identical ratios wherever possible. Challenge infections with
757 virulent *Salmonella* were carried out between 9 and 12 weeks of age. As strong
758 phenotypes were expected, we adhered to standard practice of analysing at least 5 mice
759 per group. Researchers were not blinded to group allocation.

760

761 **Strains and plasmids**

762 All strains and plasmids used in this study are listed **Table S1**.

763 For cultivation of bacteria, we used lysogeny broth (LB) containing appropriate
764 antibiotics (i.e., 50 µg/ml streptomycin (AppliChem); 6 µg/ml chloramphenicol
765 (AppliChem); 50 µg/ml kanamycin (AppliChem); 100 µg/ml ampicillin (AppliChem)).
766 Dilutions were prepared in Phosphate Buffer Saline (PBS, Difco).

767 In-frame deletion mutants (e.g. *gtrC::cat*) were performed by λ *red* recombination as
768 described in⁴³. When needed, antibiotic resistance cassettes were removed using the
769 temperature-inducible FLP recombinase encoded on pCP20⁴³. Mutations coupled with
770 antibiotic resistance cassettes were transferred into the relevant genetic background by
771 generalized transduction with bacteriophage P22 HT105/1 *int-201*⁴⁴. Primers used for
772 genetic manipulations and verifications of the constructions are listed **Table S2**.
773 Deletions of *gtrA* and *gtrC* originated from in-frame deletions made in *S.Tm* 14028S,
774 kind gifts from Prof. Michael McClelland (University of California, Irvine), and were
775 transduced into the SB300 genetic background.

776

777 The *gtrABC* operon (STM0557-0559) was cloned into the pSC101 derivative plasmid
778 pM965⁴⁵ for constitutive expression. The operon *gtrABC* was amplified from the
779 chromosome of SB300 using the Phusion Polymerase (ThermoFisher Scientific) and
780 primers listed **Table S2**. The PCR product and pM965 were digested with PstI-HF and
781 EcoRV-HF (NEB) before kit purification (SV Gel and PCR Clean up System, Promega)
782 and ligation in presence of T4 ligase (NEB) following manufacturer recommendations.
783 The ligation product was transferred by electro-transformation in competent SB300
784 cells.

785

786 **Targeted sequencing**

787 Targeted re-sequencing by the Sanger method (Microsynth AG) was performed on kit
788 purified PCR products (Promega) from chromosomal DNA or expression vector
789 templates using pre-mixed sequencing primers listed **Table S2**.

790

791 **Whole-genome re-sequencing of O:12^{Bimodal} isolates**

792 The genomes of *S.Tm* and evolved derivatives were fully sequenced by the Miseq
793 system (2x300bp reads, Illumina, San Diego, CA) operated at the Functional Genomic
794 Center in Zürich. The sequence of *S.Tm* SL1344 (NC_016810.1) was used as reference.

795 Quality check, reads trimming, alignments, SNPs and indels calling were performed
796 using the bioinformatics software CLC Workbench (Qiagen).

797

798 **Whole-genome sequencing of *S.Tm* isolates from "Evolutionary Trap" vaccinated** 799 **mice and variant calling.**

800 Nextera XT libraries were prepared for each of the samples. The barcoded libraries
801 were pooled into equimolar concentrations following manufacturer's guidelines
802 (Illumina, San Diego, CA) using the Mid-Output Kit for paired-end sequencing (2×150
803 bp) on an Illumina NextSeq500 sequencing platform. Raw data (mean virtual coverage
804 361x) was demultiplexed and subsequently clipped of adapters using Trimmomatic
805 v0.38 with default parameters⁴⁶. Quality control passing read-pairs were aligned against
806 reference genome/plasmids (Accession numbers: NC_016810.1, NC_017718.1,
807 NC_017719.1, NC_017720.1) with bwa v0.7.17⁴⁷. Genomic variant were called using
808 Pilon v1.23⁴⁸. with the following parameters: (i) minimum coverage 10x; (ii) minimum
809 quality score = 20; (iii) minimum read mapping quality = 10. SnpEff v4.3 was used to
810 annotate variants according to NCBI and predict their effect on genes⁴⁹.

811

812 **PA-STm vaccinations**

813 Peracetic acid killed vaccines were produced as previously described²⁸. Briefly,
814 bacteria were grown overnight to late stationary phase, harvested by centrifugation and
815 re-suspended to a density of 10⁹-10¹⁰ per ml in sterile PBS. Peracetic acid (Sigma-
816 Aldrich) was added to a final concentration of 0.4% v/v. The suspension was mixed
817 thoroughly and incubated for 60 min at room temperature. Bacteria were washed once
818 in 40 ml of sterile 10x PBS and subsequently three times in 50 ml sterile 1x PBS. The
819 final pellet was re-suspended to yield a density of 10¹¹ particles per ml in sterile PBS
820 (determined by OD600) and stored at 4°C for up to three weeks. As a quality control,
821 each batch of vaccine was tested before use by inoculating 100 µl of the killed vaccine
822 (one vaccine dose) into 300 ml LB and incubating over night at 37 °C with aeration.
823 Vaccine lots were released for use only when a negative enrichment culture had been
824 confirmed. For all vaccination, 10¹⁰ particles, suspended in 100µl PBS were delivered
825 by oral gavage, once weekly for 4 weeks. Where multiple strains were combined, the
826 total number of vaccine particles remained constant, and was roughly equally divided
827 between the constituent strains. Unless otherwise stated, PA-STm vaccinated mice were
828 challenged orally on d28 after the first vaccination.

829

830 **Adoptive transfer of recombinant mSTA121 IgA**

831 A recombinant monoclonal dimeric murine IgA specific for the O:12-0 epitope
832 (described in ¹⁵) was buffer-exchanged into sterile PBS. 1 mg of antibody was injected
833 intravenously into mice 30 min prior to infection and again 12 h post-infection, to
834 maintain sufficient dimeric IgA for export into the gut by PIgR.

835

836 **Chronic infection with live-attenuated vaccine strains of non-typhoidal *Salmonella***

837 6-week-old mice were orally pretreated 24 h before infection with 25 mg streptomycin.
838 Live-attenuated strains (*sseD::aphT*, *ΔgrtC ΔaroA* and *ΔoafA ΔgrtC ΔaroA*, **Table S1**,

839 ⁵⁰) were cultivated overnight separately in LB containing streptomycin. Subcultures
840 were prepared before infections by diluting overnight cultures 1:20 in fresh LB without
841 antibiotics and incubation for 4 h at 37°C. The cells were washed in PBS, diluted, and
842 50 µl of resuspended pellets were used to infect mice *per os* (5×10^7 CFU).
843 Feces were sampled at day 1, 9 and 42 post-infection, homogenized in 1 ml PBS by
844 bead beating (3mm steel ball, 25 Hz for 1 minute in a TissueLyser (Qiagen)), and *S.Tm*
845 strains were enumerated by selective plating on MacConkey agar supplemented with
846 streptomycin. Samples for lipocalin-2 measurements were kept homogenized in PBS at
847 -20 °C. Enrichment cultures for analysis of O-antigen composition were carried out by
848 inoculating 2 µl of fecal slurry into 5ml of fresh LB media and cultivating overnight at
849 37 °C.

850

851 **Non-typhoidal *Salmonella* challenge infections**

852 Infections were carried out as previously described ²³. In order to allow reproducible
853 gut colonization, 8-12 week-old SPF mice, naïve or PA-STm vaccinated, were orally
854 pretreated 24 h before infection with 25 mg streptomycin or 20 mg of ampicillin. Strains
855 were cultivated overnight separately in LB containing the appropriate antibiotics.
856 Subcultures were prepared before infections by diluting overnight cultures 1:20 in fresh
857 LB without antibiotics and incubation for 4 h at 37°C. The cells were washed in PBS,
858 diluted, and 50 µl of resuspended pellets were used to infect mice *per os* (5×10^5 CFU).
859 Competitions were performed by inoculating 1:1 mixtures of each competitor strain.
860 Feces were sampled daily, homogenized in 1 ml PBS by bead beating (3 mm steel ball,
861 25 Hz for 1 min in a TissueLyser (Qiagen)), and *S.Tm* strains were enumerated by
862 selective plating on MacConkey agar supplemented with the relevant antibiotics. Fecal
863 samples for lipocalin-2 measurements were kept homogenized in PBS at -20°C. At
864 endpoint, intestinal lavages were harvested by flushing the ileum content with 2 ml of
865 PBS using a cannula. The mesenteric lymph nodes, were collected, homogenized in
866 PBS Tergitol 0.05% v/v at 25 Hz for 2 min, and bacteria were enumerated by selective
867 plating.

868 Competitive indexes were calculated as the ratio of population sizes of each genotype,
869 enumerated by selective plating of the two different strains on kanamycin- and
870 chloramphenicol-containing agar, at a given time point, normalized for the ratio
871 determined by selective plating in the inoculum (which was always between 0.5 and 2).

872

873 **Non-typhoidal *Salmonella* transmission**

874 Donor mice were vaccinated with PA-*S.Tm* ^{Δ oafA Δ gtrC} once per week for 5 weeks,
875 streptomycin pretreated (25 mg streptomycin *per os*), and gavaged 24 h later with 10^5
876 CFU of a 1:1 mixture of *S. Tm* ^{Δ oafA Δ gtrCwzyB::cat} (Cm^R) and *S. Tm* ^{Δ oafA Δ gtrC}Kan (Kan^R). On
877 day 4 post infection, the donor mice were euthanized, organs were harvested, and fecal
878 pellets were collected, weighed and homogenized in 1 ml of PBS. The re-suspended
879 feces (centrifuged for 10 s to discard large debris) were immediately used to gavage (as
880 a 50 µl volume containing the bacteria from on fecal pellet) recipient naïve mice
881 (pretreated with 25 mg streptomycin 24 hours before infection). Recipient mice were
882 euthanized and organs were collected on day 2 post transmission. In both donor and

883 recipient mice, fecal pellets were collected daily and selective plating was used to
884 enumerate *Salmonella* and determine the relative proportions (and consequently the
885 competitive index) of both competing bacterial strains.

886

887 **Quantification of fecal Lipocalin2**

888 Fecal pellets collected at the indicated time-points were homogenized in PBS by bead-
889 beating at 25 Hz, 1min. Large particles were sedimented by centrifugation at 300 g, 1
890 min. The resulting supernatant was then analysed in serial dilution using the mouse
891 Lipocalin2 ELISA duoset (R&D) according to the manufacturer's instructions.

892

893 **Analysis of specific antibody titres by bacterial flow cytometry**

894 Specific antibody titres in mouse intestinal washes were measured by flow cytometry
895 as described^{15,51}. Briefly, intestinal washes were collected by flushing the small
896 intestine with 2 ml PBS, centrifuged at 16000 g for 30 min to clear all bacterial-sized
897 particles. Aliquots of the supernatants were stored at -20°C until analysis. Bacterial
898 targets (antigen against which antibodies are to be titred) were grown to late stationary
899 phase or the required OD in 0.2µm-filtered LB, then gently pelleted for 2 min at 7000
900 g. The pellet was washed with 0.2µm-filtered 1% BSA/PBS before re-suspending at a
901 density of approximately 10⁷ bacteria per ml. After thawing, intestinal washes were
902 centrifuged again at 16000 g for 10 min to clear. Supernatants were used to perform
903 serial dilutions. 25 µl of the dilutions were incubated with 25 µl bacterial suspension at
904 4°C for 1 h. Bacteria were washed twice with 200 µl 1% BSA/PBS by centrifugation at
905 7000g for 15 min, before resuspending in 25 µl of 0.2µm-filtered 1% BSA/PBS
906 containing monoclonal FITC-anti-mouse IgA (BD Pharmingen, 10 µg/ml) or Brilliant
907 violet 421-anti-IgA (BD Pharmingen, 10µg/ml). After 1 h of incubation, bacteria were
908 washed once with 1% BSA/PBS as above and resuspended in 300 µl 1% BSA/PBS for
909 acquisition on LSRII or Beckman Coulter Cytoflex S using FSC and SSC parameters
910 to threshold acquisition in logarithmic mode. Data were analysed using FloJo
911 (Treestar). After gating on bacterial particles, log-median fluorescence intensities
912 (MFI) were plotted against lavage dilution factor for each sample and 4-parameter
913 logistic curves were fitted using Prism (Graphpad, USA). Titers were calculated from
914 these curves as the dilution factor giving an above-background signal (typically IgA
915 coating MFI=1000 – e.g. Fig. S7 and S8).

916

917 **Dirty-plate ELISA analysis of intestinal lavage IgA titres specific for *S.Tm*.**

918 Bacterial targets (antigen against which antibodies are to be titred) were grown to late
919 stationary phase in 0.2µm-filtered LB, then gently pelleted for 2 min at 7000 g. The
920 pellet was washed with 0.2µm-filtered 1% BSA/PBS before re-suspending at a density
921 of approximately 10⁹ bacteria per ml in sterile PBS. 50µl of this bacterial suspension
922 was added to each well of a Nunc Immunosorb ELISA plate and was incubated
923 overnight at 4°C in a humidified chamber. The ELISA plates were then washed 3 times
924 with PBS/0.5% Tween-20 and blocked with 200µl per well of 2% BSA in PBS for 3h.
925 After thawing, intestinal washes were centrifuged again at 16000 g for 10 min to clear.
926 Supernatants were used to perform serial dilutions. 50 µl of the dilutions were added to

927 each well and the plates were incubated at 4°C overnight in a humidified chamber. The
928 next morning, the plates were washed 5 times with PBS/0.5% Tween-20 and 50µl of
929 HRP-anti-mouse-IgA (Sigma-Aldrich, 1:1000) was added to each well. This was
930 incubated for 1h at room temperature before washing again 5 times and developing the
931 plates with 100µl per well of ABTS ELISA substrate. Absorbance at 405nm was read
932 using a Tecan Infinite pro 200. A₄₀₅ readings were plotted against lavage dilution factor
933 for each sample and 4-parameter logistic curves were fitted using Prism (Graphpad,
934 USA). Titers were calculated from these curves as the dilution factor giving an above-
935 background signal (A₄₀₅=0.2 – e.g. Fig. S7 and S8).

936

937 **Flow cytometry for analysis of O:5, O:4 and O:12-0 epitope abundance on** 938 ***Salmonella* in cecal content, enrichment cultures and clonal cultures**

939 1 µl of overnight cultures made in 0.2µm-filtered LB, or 1µl of fresh feces or cecal
940 content suspension (as above) was stained with 0.2µm-filtered solutions of STA5
941 (human recombinant monoclonal IgG2 anti-O:12-0, 6µg/ml¹⁵), Rabbit anti-*Salmonella*
942 O:5 (Difco, 1:200) or Rabbit anti-*Salmonella* O:4 (Difco, 1:5). After incubation at 4°C
943 for 30 min, bacteria were washed twice by centrifugation at 7000g and resuspension in
944 PBS/1% BSA. Bacteria were then resuspended in 0.2µm-filtered solutions of
945 appropriate secondary reagents (Alexa 647-anti-human IgG, Jackson ImmunoResearch
946 1:200, Brilliant Violet 421-anti-Rabbit IgG, Biolegend 1:200). This was incubated for
947 10-60 min before cells were washed as above and resuspended for acquisition on a BD
948 LSRII or Beckman Coulter Cytoflex S. A media-only sample was run on identical
949 settings to ensure that the flow cytometer was sufficiently clean to identify bacteria
950 without the need for DNA dyes. Median fluorescence intensity corresponding to O:12-
951 0 or O:5 staining was calculated using FlowJo (Treestar, USA). Gates used to calculate
952 the % of "ON" and "OFF" cells were set by gating on samples with known O:5/O:4
953 (*oafA*-deletion) and O:12-0 (*gtrC*-deletion) versus O:12-2 (*pgtrABC*) phenotypes (Fig.
954 S2 and 3).

955

956 **Live-cell immunofluorescence**

957 200 uL of an overnight culture was centrifuged and resuspended in 200 µL PBS
958 containing 1 µg recombinant murine IgA clone STA121-AlexaFluor568. The cells and
959 antibodies were co-incubated for 20 min at room temperature in the dark and then
960 washed twice in 1 mL Lysogeny broth (LB). Antibody-labeled cells were pipetted into
961 an in-house fabricated microfluidic device⁵². Cells in the microfluidic device were
962 continuously fed *S.Tm*-conditioned LB⁵² containing STA121-AlexaFluor568 (1
963 µg/mL). Media was flowed through the device at a flow rate of 0.2 mL/h using syringe
964 pumps (NE-300, NewEra PumpSystems). Cells in the microfluidic device were imaged
965 on an automated Olympus IX81 microscope enclosed in an incubation chamber heated
966 to 37°C. At least 10 unique positions were monitored in parallel per experiment. Phase
967 contrast and fluorescence images were acquired every 3 min. Images were
968 deconvoluted in MatLab⁵³. Videos are compressed to 7 fps, i.e. 1 s = 21 mins.

969

970 **HR-MAS NMR**

971 *S. Typhimurium* cells were grown overnight (~18 h) to late stationary phase. The
972 equivalent of 11–15 OD₆₀₀ was pelleted by centrifugation for 10 min 4 °C and 3750 g.
973 The pellet was resuspended in 10% NaN₃ in potassium phosphate buffer (PPB; 10 mM
974 pH 7.4) in D₂O and incubated at room temperature for at least 90 min. The cells were
975 then washed twice with PPB and resuspended in PPB to a final concentration of 0.2
976 OD₆₀₀/μl in PPB containing acetone (final concentration 0.1% (v/v) as internal
977 reference). The samples were kept on ice until the NMR measurements were performed
978 - i.e. for between 1 and 8 h. The HR-MAS NMR spectra were recorded in two batches,
979 as follows: *S.Tm*^{WT}, *S.Tm*^{ΔwbaP}, *S.Tm*^{Evolved_1}, *S.Tm*^{Evolved_2} were measured on
980 16.12.2016, *S.Tm*^{ΔoafA} was measured on 26.7.2017.

981
982 NMR experiments on intact cells were carried out on a Bruker Biospin AVANCE III
983 spectrometer operating at 600 MHz ¹H Larmor frequency using a 4 mm HR-MAS
984 Bruker probe with 50 μl restricted-volume rotors. Spectra were collected at a
985 temperature of 27 °C and a spinning frequency of 3 kHz except for the sample of
986 *S.Tm*^{ΔoafA} (25°C, 2 kHz). The ¹H experiments were performed with a 24 ms Carr–
987 Purcell–Meiboom–Gill (CPMG) pulse-sequence with rotor synchronous refocusing
988 pulses every two rotor periods before acquisition of the last echo signal to remove broad
989 lines due to solid-like material⁵⁴. The 90° pulse was set to 6.5 μs, the acquisition time
990 was 1.36 s, the spectral width to 20 ppm. The signal of HDO was attenuated using water
991 pre-saturation for 2 s. 400 scans were recorded in a total experimental time of about 30
992 minutes.

993 **O-Antigen purification and ¹H-NMR**

994 The LPS was isolated applying the hot phenol-water method⁵⁵, followed by dialysis
995 against distilled water until the phenol scent was gone. Then samples were treated with
996 DNase (1mg/100 mg LPS) plus RNase (2 mg/100 mg LPS) at 37°C for 2 h, followed
997 by Proteinase K treatment (1 mg/100 mg LPS) at 60°C for 1 h [all enzymes from Serva,
998 Germany]. Subsequently, samples were dialyzed again for 2 more days, then freeze
1000 dried. Such LPS samples were then hydrolyzed with 1% aqueous acetic acid (100°C,
1001 90 min) and ultra-centrifuged for 16 h at 4°C and 150,000 g. Resulting supernatants
1002 (the O-antigens) were dissolved in water and freeze-dried. For further purification, the
1003 crude O-antigen samples were chromatographed on TSK HW-40 eluted with
1004 pyridine/acetic acid/water (10/4/1000, by vol.), then lyophilized. On these samples, 1D
1005 and 2D (COSY, TOCSY, HSQC, HMBC) ¹H- and ¹³C-NMR spectra were recorded
1006 with a Bruker DRX Avance 700 MHz spectrometer (¹H: 700.75 MHz; ¹³C: 176.2 MHz)
1007 as described⁵⁶.

1008

1009 **Atomic force microscopy**

1010 The indicated *S.Tm* strains were grown to late-log phase, pelleted, washed once with
1011 distilled water to remove salt. A 20 μl of bacterial solution was deposited onto freshly
1012 cleaved mica, adsorbed for 1 min and dried under a clean airstream. The surface of
1013 bacteria was probed using a Dimension FastScan Bio microscope (Bruker) with Bruker

1014 AFM cantilevers in tapping mode under ambient conditions. The microscope was
1015 covered with an acoustic hood to minimized vibrational noise. AFM images were
1016 analyzed using the Nanoscope Analysis 1.5 software.

1017

1018 **Methylation analysis of *S.Tm* clones**

1019 For REC-Seq (restriction enzyme cleavage–sequencing) we followed the same
1020 procedure described by Ardisson et al, 2016⁵⁷. In brief, 1 µg of genomic DNA from
1021 each *S.Tm* was cleaved with MboI, a blocked (5'biotinylated) specific adaptor was
1022 ligated to the ends and the ligated fragments were then sheared to an average size of
1023 150-400 bp (Fasteris SA, Geneva, CH). Illumina adaptors were then ligated to the
1024 sheared ends followed by deep-sequencing using a HiSeq Illumina sequencer, the 50
1025 bp single end reads were quality controlled with FastQC v0.9
1026 (<http://www.bioinformatics.babraham.ac.uk/projects/fastqc/>). To
1027 remove contaminating sequences, the reads were split according to the MboI consensus motif
1028 (5'-GATC-3') considered as a barcode sequence using fastx_toolkit v0.0.13.2
1029 (http://hannonlab.cshl.edu/fastx_toolkit/) (fastx_barcode_splitter.pl --bcfile
1030 barcodelist.txt --bol --exact). A large part of the reads (60%) were rejected and 40%
1031 kept for remapping to the reference genomes with bwa mem⁴⁷ v0.7.15 and samtools⁵⁸
1032 v0.1.19 to generate a sorted bam file. The bam file was further filtered to remove low
1033 mapping quality reads (keeping AS >= 45) and split by orientation (alignmentFlag 0 or
1034 16) with bamtools⁵⁹ v2.4.1. The reads were counted at 5' positions using Bedtools⁶⁰
1035 v2.26.0 (bedtools genomecov -d -5). Both orientation count files were combined into a
1036 bed file at each identified 5'-GATC-3' motif using PERL script (perl v5.24). The MboI
1037 positions in the bed file were associated with the closest gene using bedtools closest⁶⁰
1038 v2.26.0 and the gff3 file of the reference genomes⁶¹. The final bed file was converted
1039 to an MS Excel sheet. The counts were loaded in RStudio v1.1.442⁶² with R v3.4.4⁶³
1040 and analysed with the DESeq2 v1.18.1 package⁶⁴ comparing the reference strain with
1041 the 3 evolved strains considered as replicates. The counts are analysed by genome
1042 position rather than by gene. The positions are considered significantly differentially
1043 methylated upon an adjusted p-value < 0.05. Of the 2607 GATC positions, only 4 were
1044 found significantly differentially methylated and they are all located in the promoter of
1045 the *gtrABC* operon.

1046 The first step in the reads filtering was to remove contaminant reads missing the GATC
1047 consensus motif (MboI) at the beginning of the sequence. These contaminant reads are
1048 due to random fragmentation of the genomic DNA and not to cuts of the MboI
1049 restriction enzyme. Using fastx_barcode_splitter.pl v0.0.13.2 about 60% of the
1050 reads were rejected because they did not start with GATC. The rest (40%) was
1051 analyzed further. Random DNA shearing and blunt-ended ligation of adaptors,
1052 combined with sequencing noise at the beginning of reads likely generates this high
1053 fraction of reads missing at GTAC sequence.

1054

1055 ***gtrABC* expression analysis by blue/white screening and flow cytometry.**

1056 About 200 colonies of *S.Tm*^{*gtrABC-lacZ*} (strain background 4/74, ⁴) were grown from an
1057 overnight culture on LB agar supplemented with X-gal (0.2 mg/ml, Sigma) in order to

1058 select for *gtrABC* ON (blue) and OFF clones (white). These colonies were then picked
1059 to start pure overnight cultures. These cultures were diluted and plated on fresh LB agar
1060 X-gal plate in order to enumerate the proportion of *gtrABC* ON and OFF siblings. The
1061 proportion of O:12/O:12-2 cells was analyzed by flow cytometry.

1062

1063 ***In vitro* growth and competitions to determine *wzyB*-associated fitness costs**

1064 Single or 1:1 mixed LB subcultures were diluted 1000 times in 200 μ l of media
1065 distributed in 96 well black side microplates (Costar). Where appropriate, wild type
1066 *S.Tm* carried a plasmid for constitutive expression of GFP. To measure growth and
1067 competitions in stressful conditions that specifically destabilize the outer membrane of
1068 *S.Tm*, a mixture of Tris and EDTA (Sigma) was diluted to final concentration (4 mM
1069 Tris, 0.4 mM EDTA) in LB; Sodium cholate (Sigma) and Sodium Dodecyl Sulfate
1070 (SDS) (Sigma) were used at 2% and 0.05% final concentration respectively. The lid-
1071 closed microplates were incubated at 37°C with fast and continuous shaking in a
1072 microplate reader (Synergy H4, BioTek Instruments). The optical density was
1073 measured at 600 nm and the green fluorescence using 491 nm excitation and 512 nm
1074 emission filter wavelengths every 10 minutes for 18 h. Growth in presence of SDS
1075 causes aggregation when cell density reaches OD=0.3-0.4, therefore, it is only possible
1076 to compare the growth curves for about 250 minutes. The outcome of competitions was
1077 determined by calculating mean OD and fluorescence intensity measured during the
1078 last 100 min of incubation. OD and fluorescence values were corrected for the baseline
1079 value measured at time 0.

1080

1081 **Serum resistance**

1082 Overnight LB cultures were washed three times in PBS, OD adjusted to 0.5 and
1083 incubated with anonymized pooled human serum obtained from Unispital Basel (3 vol
1084 of culture for 1 vol of serum) at 37°C for 1 h. Heat inactivated (56°C, 30 min) serum
1085 was used as control treatment. Surviving bacteria were enumerated by plating on non-
1086 selective LB agar plates. For this, dilutions were prepared in PBS immediately after
1087 incubation.

1088

1089 **Bacteriophage sensitivity tests:**

1090 5 ml sewage water (sewage plant inflow treated with 1 % v/v chloroform; Basel Stadt,
1091 Switzerland) were mixed with 500 μ l of dense bacterial culture (ancestor wild type *S.*
1092 *Tm*; evolved short O-antigen *wzyB* mutant AE860.3, *S.Tm*^{*AgtrC oafA::cat*}, *S.Tm*^{*AgtrC Δ oafA*}
1093 *wzyB::cat*), incubated for 15 minutes at 37 °C. The mixtures were added to 15 ml LB
1094 containing 10 mM CaCl₂, 10 mM MgSO₄ and 0.7 % w/v agar, and immediately poured
1095 onto LB agar plates with the appropriate antibiotics.

1096

1097 Sensitivity to isolated phage ϕ 12 was quantified by calculating phage titres obtained
1098 after overnight cultures of evolved short O-antigen *wzyB* mutant AE860.3 or ancestor
1099 wild type *S. Tm* in presence of the isolated bacteriophage (MOI=10).

1100

1101 **Isolation of bacteriophages and resistant clones:**

1102 Plaques with different morphologies appearing on *S.Tm^{AgtrC ΔoafA wzyB::cat}* plates were
1103 streaked on overlay plates containing *S.Tm^{AgtrC ΔoafA wzyB::cat}*. The resulting plaques were
1104 used to inoculate 200 μl of a *S.Tm^{AgtrC ΔoafA wzyB::cat}* culture at OD₆₀₀=0.3 in a 96-well
1105 plate and optical density was measured every 10 minutes at 37 °C with shaking in a
1106 Synergy 2 plate-reader. Well contents after 18 hours of growth were streaked onto LB-
1107 Cm plates to isolate bacterial colonies from the regrowing population. Resistance to
1108 phage was confirmed by testing for absence of plaque formation in presence of the
1109 corresponding phage.

1110 The rest of the well contents were cleared by centrifugation and filtered (0.45 μm) for
1111 phage purification. The cleared supernatants were used to inoculate 20 ml of a *S.Tm^{AgtrC}*
1112 *ΔoafA wzyB::cat* culture at OD₆₀₀=0.3 and subsequently grown at 37 °C for 5 hours. Cell
1113 debris was removed by centrifugation, the supernatants cleared by 0.45 μm filtration
1114 and stored at 4 °C.

1115

1116 **Phage genome sequencing and analysis:**

1117 Phage DNA was isolated using the Phage DNA Isolation Kit from Norgen Biotek and
1118 sequenced at MiGS, Pittsburgh, Pennsylvania, USA. For this, Nextera libraries were
1119 prepared for each sample and sequenced on an Illumina NextSeq 550 sequencing
1120 platform to generate paired end reads.

1121 De novo genome assembly was performed using the De Novo Assembly Algorithm of
1122 CLC Genomics Workbench and the resulting high coverage contigs were aligned
1123 using the Whole Genome Alignment Plug-In to calculate neighbor-joining trees and
1124 corresponding pairwise comparison tables.

1125 Assembly of the phage genomes resulted in a single contig of 108,227 bp and 114,055
1126 bp for φ12 and φ23, respectively (4,928 and 4,495-fold coverage). For φ34 four separate
1127 contigs with more than 3000-fold coverage were identified (81,319, 12,250, 10,937,
1128 5,594 bp), giving a total genome size of more than 100,100 bp, while for φ37 three
1129 contigs with more than 1600-fold coverage (95,133, 14,559, 4,197 bp) gave a total
1130 genome size of at least 113,889 bp.

1131 For comparison, enterobacteria phage T5 has a double-stranded linear DNA genome of
1132 121,750 bp.

1133

1134 **Modeling antigen switching between O12 and O12-2**

1135 The aim of this modeling approach is to test whether a constant switching rate between
1136 an O12 and an O12-2 antigen expression state can explain the experimentally observed
1137 bimodal populations.

1138

1139 To this end, we formulated a deterministic model of population dynamics of the two
1140 phenotypic states as:

1141

$$1142 \quad \frac{dO_{12}}{dt} = (\mu O_{12} - s_{\rightarrow 12-2} O_{12} + s_{\rightarrow 12} O_{12-2}) * \left(1 - \frac{(O_{12} + O_{12-2})}{K} \right)$$

1143

$$1144 \quad \frac{dO_{12-2}}{dt} = (\mu O_{12-2} + s_{\rightarrow 12-2} O_{12} - s_{\rightarrow 12} O_{12-2}) * \left(1 - \frac{(O_{12} + O_{12-2})}{K} \right)$$

1145

1146 where O_{12} and O_{12-2} denote the population sizes of the respective antigen variants, μ
1147 denotes the growth rate, which is assumed to be identical for the two variants, K
1148 carrying capacity, and $s_{\rightarrow 12-2}$ and $s_{\rightarrow 12}$ the respective switching rates from O_{12} to
1149 O_{12-2} and from O_{12-2} to O_{12} . Growth, as well as the antigen switching rates, are scaled
1150 with population size in a logistic way, so that all processes come to a halt when carrying
1151 capacity is reached.

1152

1153 We use the model to predict the composition of a population after growth in LB
1154 overnight, and therefore set the specific growth rate to $\mu = 2.05h^{-1}$, which
1155 corresponds to a doubling time of roughly 20min. The carrying capacity is set to $K =$
1156 10^9 cells. We ran parameter scans for the switching rates $s_{\rightarrow 12}$ and $s_{\rightarrow 12-2}$, with
1157 population compositions that start either with 100% or 0% O_{12} , and measure the
1158 composition of the population after 16h of growth (**Fig. S11C**). The initial population
1159 size is set to 10^4 cells

1160

1161 Experimentally, we observe that when starting a culture with an O_{12} colony, after
1162 overnight growth the culture is composed of around 90% O_{12} and 10% O_{12-2} cells,
1163 whereas starting the culture with O_{12-2} cells yields around 50% O_{12} and 50% O_{12-2}
1164 cells after overnight growth (**Fig. S11B**). To explain this observation without a change
1165 in switching rates, we would need a combination of values in $s_{\rightarrow 12}$ and $s_{\rightarrow 12-2}$ that
1166 yield the correct population composition for both scenarios. In **Fig. S11D**, we plot the
1167 values of $s_{\rightarrow 12}$ and $s_{\rightarrow 12-2}$ that yield values of 10% O_{12-2} (starting with 0% O_{12-2} ,
1168 green dots) and 50% O_{12-2} (starting with 100% O_{12-2} , orange dots). The point clusters
1169 intersect at $s_{\rightarrow 12} = 0.144h^{-1}$ and $s_{\rightarrow 12-2} = 0.037h^{-1}$ (as determined by a local linear
1170 regression at the intersection point).

1171

1172 We then used the thus determined switching rates to produce a population growth curve
1173 in a deterministic simulation, using the above equations for a cultures starting with
1174 100% O_{12-2} , (**Fig. S11E**, Left-hand graph) and for a culture starting with 0% O_{12-2}
1175 (**Fig. S11E**, right-hand graph).

1176

1177 These switching rates are consistent with published values⁴. Our results show that the
1178 observed phenotype distributions can be explained without a change in the rate of
1179 switching between the phenotypes.

1180

1181 **Data availability**

1182 All Plotted data and associated raw numerical data and calculations for figure 1-4,
1183 extended data fig. 1-10 and supplementary figures 1-10 is provided in source data tables
1184 (one per figure, titled accordingly). Uncropped images are provided as supplementary
1185 files.

1186 All raw flow cytometry data, ordered by figure, is publically available via the ETH
1187 research collection doi: 10.3929/ethz-b-000477737

1188 All Illumina sequencing data data is publically available at NCBI BioProject
1189 Accession: PRJNA720270

1190

1191 **Code availability**

1192 R code used to generate the figures shown in extended data figure 5 can be freely
1193 downloaded from <https://github.com/marnoldini/evotrap>

1194

Extended Data Fig. 1: Surface phenotype of *S.Tm* mutants

1196 **Fig. ED1: Surface phenotype of *S. Tm* mutants: A-C.** Atomic force microscopy phase
1197 images of *S. Tm*^{wt}, *S. Tm*^{ΔwzyB} (single-repeat O-antigen), and *S. Tm*^{ΔwbaP} (rough mutant
1198 - no O-antigen) at low magnification (A, uncropped image, scale bar = 1 μm) and high
1199 magnification (B and C, scale bar main image = 150nm, scale bar inset = 15nm).
1200 Invaginations in the surface of *S. Tm*^{ΔwbaP} (dark colour, B) show a geometry and size
1201 consistent with outer membrane pores⁶⁵. These are already less clearly visible on the
1202 surface of *S. Tm*^{ΔwzyB} with a single-repeat O-antigen, and become very difficult to
1203 discern in *S. Tm*^{wt}. One representative image of 3 for each genotype is shown. While
1204 arrows point to features with consistent size and abundance to be exposed outer
1205 membrane porins. C. Fast-Fourier transform of images shown in "B" demonstrating
1206 clear regularity on the surface of *S. Tm*^{ΔwbaP}, which is progressively lost when short and
1207 long O-antigen is present.
1208

B

Extended Data Fig. 2: Mutations detected in the oafa gene sequence among several strains of S. Tm

1209 **Fig. ED2: Mutations detected in the *oafA* gene sequence among several strains of**
1210 ***S.Tm*. A.** Aligned fractions of the *oafA* ORF from a natural isolate (from chicken)
1211 presenting the same 7 bp deletion detected in mutants of *S.Tm* SL1344 emerging in
1212 vaccinated mice. *S.Tm* SL1344 was used a reference⁶⁶. **B.** Aligned *oafA* promoter
1213 sequences from three natural isolates of human origin (stool or cerebrospinal fluid⁶⁷)
1214 showing variations in the number of 9 bp direct repeats.
1215

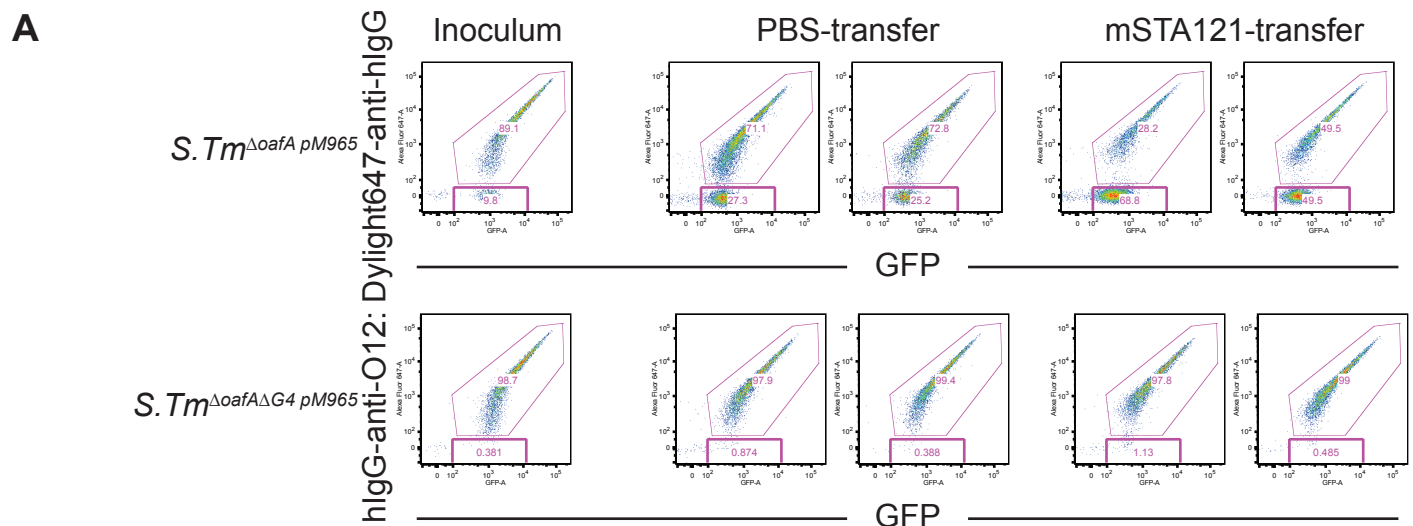

Extended Data Fig. 3: Loss of O:12-0-staining is a reversible phenotype dependent on the *gtrABC* locus STM0557-0559

1216

1217 **Fig. ED3: Loss of the O:12-0 epitope is a reversible phenotype. A.** Wild type and
1218 evolved *S.Tm* clones were picked from LB plates, cultured overnight, phenotypically
1219 characterized by O:12-0 (left panel) and O:5 staining (right panel), plated and re-picked.
1220 This process was repeated over 3 cycles with lines showing the descendants of each
1221 clone. **B and C.** Wild type 129S1/SvImJ mice were mock-vaccinated or were
1222 vaccinated with PA-*S.Tm* ^{$\Delta oafA \Delta gtrC$} as in Fig. 1. On d28, all mice were pre-treated with
1223 streptomycin, and infected with the indicated strain. **B.** Feces recovered at day 10 post-
1224 infection, was enriched overnight by culture in streptomycin, and stained for O:12-0
1225 (human monoclonal STA5). Fraction O:12-0-low *S.Tm* was determined by flow
1226 cytometry. Percentage of *S.Tm* that are O:12-0-negative was quantified over 10 days
1227 and is plotted in panel **C**. Vaccination selects for *S.Tm* that have lost the O:12-0 epitope,
1228 only if the *gtrC* gene is intact.

1229

1230

Extended Data Fig. 4. Selective pressure for O:12 phase-variation can be exerted by adoptive transfer of a monoclonal dimeric IgA.

1231 **Fig. ED4: Loss of the O:12-0 epitope can be driven by adoptive transfer of O:12-**
1232 **0-specific IgA.** C57BL/6 SPF mice received oral streptomycin to deplete the
1233 microbiota 23.5h before an intravenous injection with saline only, or with 1mg of
1234 recombinant dimeric murine IgA specific for the O:12-0 epitope (STA121). 0.5 h later
1235 all mice were orally inoculated with *S.Tm* ^{Δ oafA pM965} or *S.Tm* ^{Δ oafA Δ G4 pM965} (lacking 4
1236 different glucosyl transferases, including *gtrC*) both carrying pM965 to drive
1237 constitutive GFP production. The adoptive transfer was repeated 12h later and all
1238 animals were euthanized at 24h post-infection. **A.** O:12-0 expression on *S.Tm* enriched
1239 from cecum content by overnight culture on 1:1000 dilution LB with selective
1240 antibiotics, determined by staining with the monoclonal antibody STA5. Flow
1241 cytometry plots shown have been gated on scatter only – see Fig. S1 for example. **B.**
1242 Quantification of the O:12-0-high fraction of *S.Tm* from A. **C.** Individual clones of
1243 *S.Tm* of the indicated genotype were recovered from the cecal content of mice from A
1244 that had received an adoptive transfer of mSTA121 and individual clones, cultured
1245 overnight in LB were analysed as in A and B for fraction of O:12-0-high cells.
1246

Extended Data Fig. 5: Phase-variation and selection, without a shift in switching rate, underly recovery of O:12-2-producing clones from vaccinated mice

1247 **Fig. ED5: Phase-variation and selection, without a shift in switching rate, underly**
1248 **recovery of O:12-2 producing clones from vaccinated mice. A.** Comparison of
1249 fractions of O:12-0-positive and O:12-0-negative bacteria (in fact O:12-2) determined
1250 by flow cytometry (gating – see Fig.S1) staining with typing sera and by blue-white
1251 colony counts using a *gtrABC-lacZ* reporter strain and overnight cultures from
1252 individual clonal colonies. **B-D:** Results of a mathematical model simulating bacterial
1253 growth and antigen switching (see supplementary methods). **B.** Switching rates from
1254 O:12-0 to O:12-2 and from O:12-2 to O:12-0 were varied computationally, and the
1255 fraction of O:12-2 was plotted after 16 h of growth. Left-hand plot depicts the results
1256 of the deterministic model when starting with 100% O:12-2, right-hand plot depicts the
1257 results when starting with 100% O:12-0. **C.** depicts only the switching rates that comply
1258 with the experimentally observed antigen ratios after overnight growth (90% O:12-0
1259 when starting with O:12-0, and 50% O:12-0 when starting with O:12-2). Right-hand
1260 plot is a zoomed version showing values for switching rates between $0 - 0.2 \text{ h}^{-1}$ (marked
1261 by a grey rectangle). Dashed lines are linear regressions on the values in this range, and
1262 their intersection marks the switching rates used for the stochastic simulation in (D). **D.**
1263 Simulation results of bacterial population growth, when starting with only O:12-2 (left-
1264 hand plot) or only O:12-0 (right-hand plot). $\mu = 2.05 \text{ h}^{-1}$ was kept constant in all
1265 simulations; switching rates were kept constant at $s_{\rightarrow 12-0} = 0.144 \text{ h}^{-1}$ and $s_{\rightarrow 12-2} = 0.0365 \text{ h}^{-1}$;
1266 the starting populations were always individuals of the indicated phenotype; carrying
1267 capacity was always $K = 10^9$ cells. Time resolution for the simulations is 0.2 h .

Extended Data Fig. 6: NMR of purified LPS and HR-MAS 1H-NMR confirms O-antigen structures in evolved clones

1269 **Fig. ED6: NMR of purified LPS and HR-MAS ¹H-NMR confirms O-antigen**
1270 **structures in evolved clones. A.** Schematic diagram of expected NMR peaks for each
1271 molecular species **B.** HR-MAS ¹H-NMR spectra. Spectra show predicted peak
1272 positions and observed spectra for C1 protons of the O-antigen sugars. **C.** ¹H NMR of
1273 purified LPS from the indicated strains. Note that non-acetylated abequose can be
1274 observed in wild type strains due to spontaneous deacetylation at low pH in late
1275 stationary phase cultures⁵⁴. A *gtrA* mutant strain is used here to over-represent the O:12-
1276 2 O-antigen variant due to loss of regulation⁵.
1277

Extended Data Fig. 7: S.Tm O-antigen variants arise during chronic S.Tm infections, dependent on a specific IgA response. After 35 days of infection, this is weaker than the IgA titres induced by inactivated oral vaccines, but less biased to recognition of O:5.

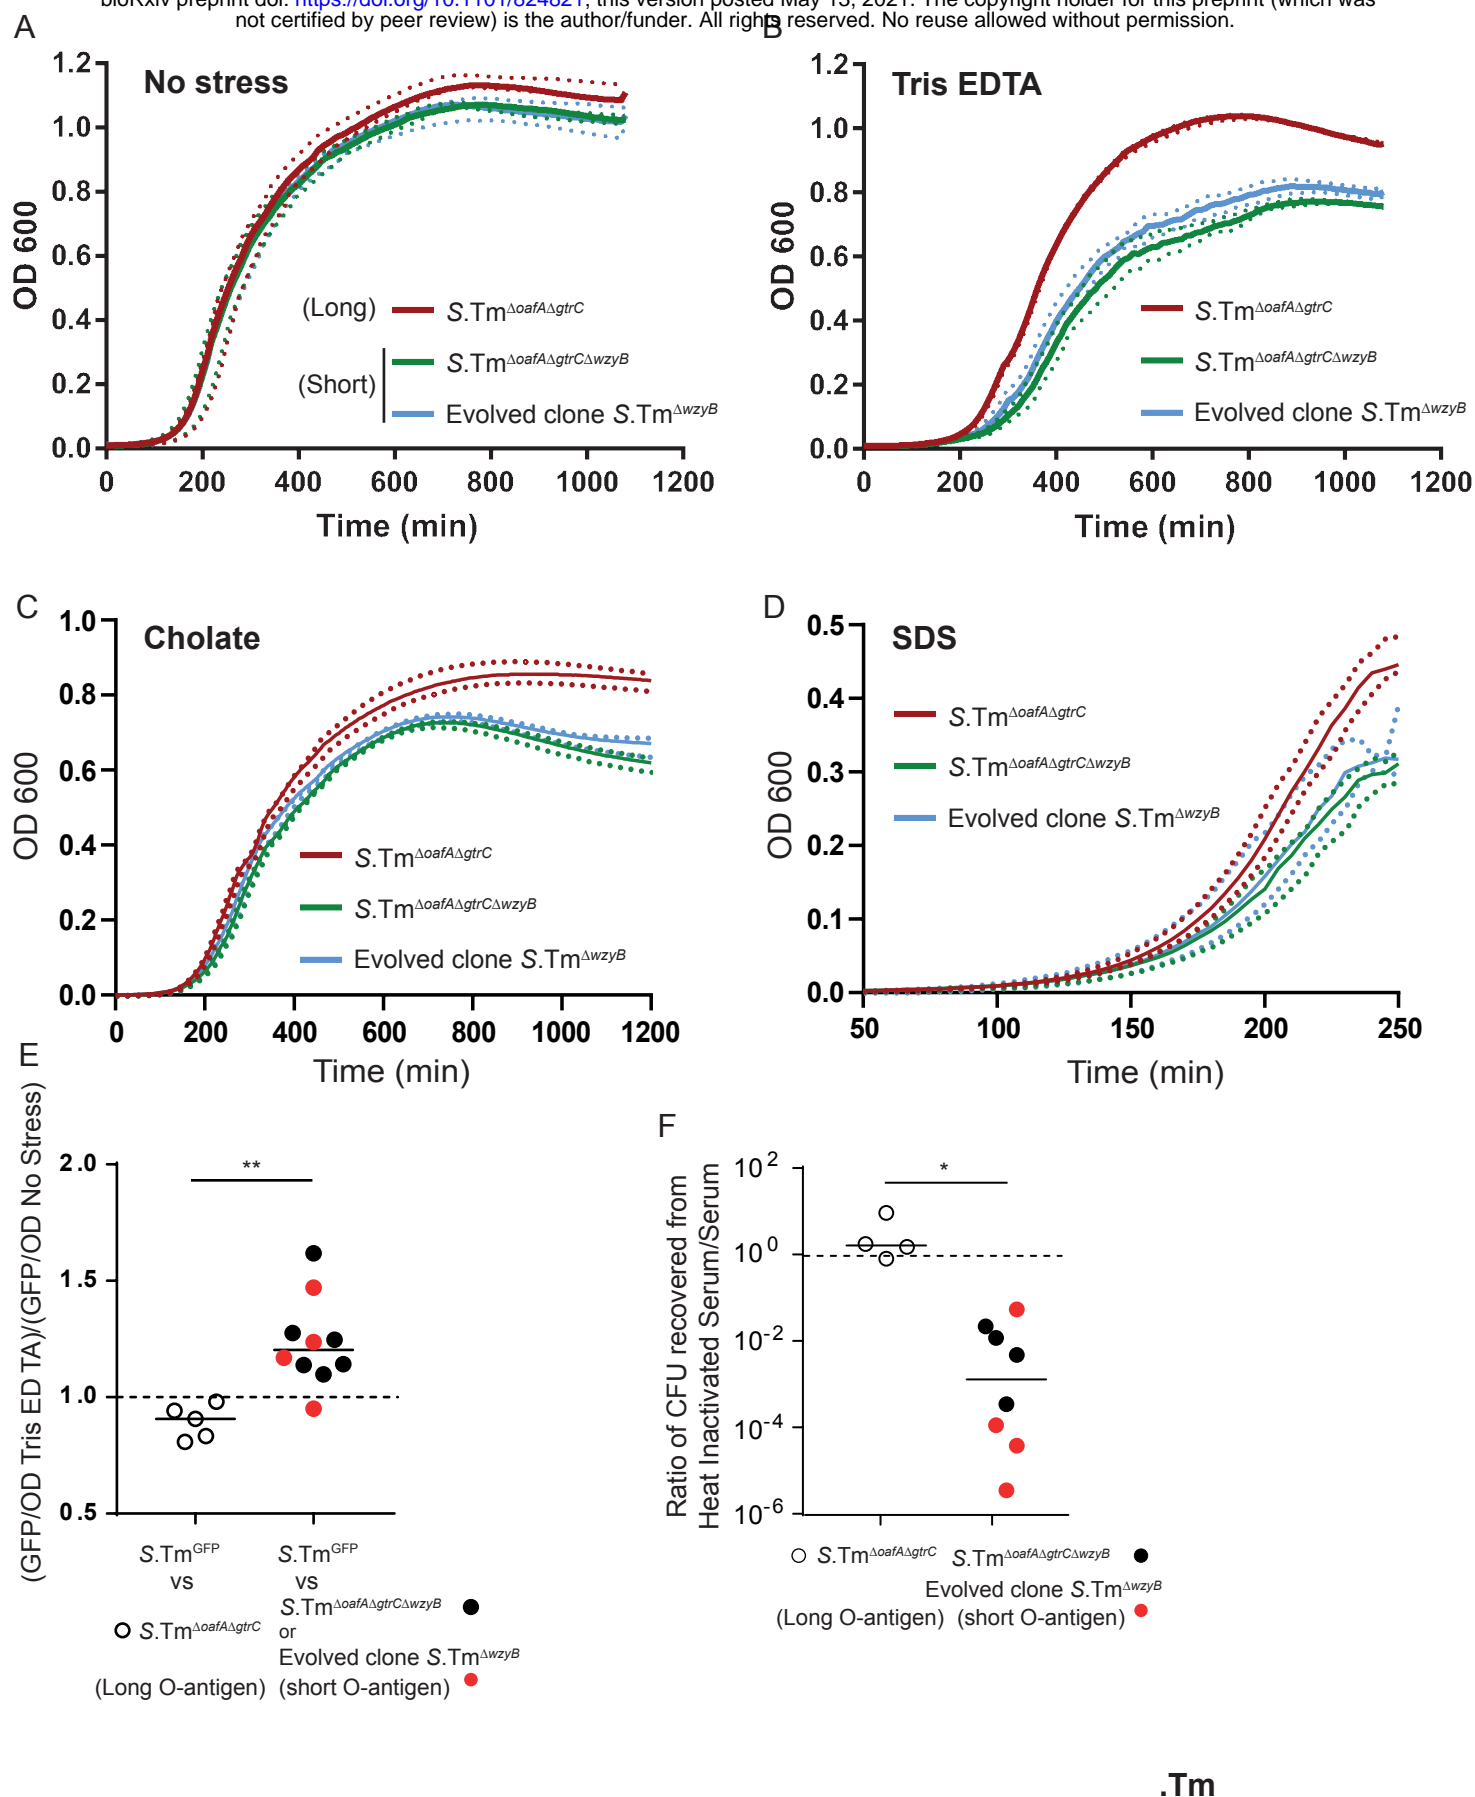

1278 **Fig ED7: S.Tm O-antigen variants arise during chronic S.Tm infections,**
1279 **dependent on a specific IgA response.** IgA^{-/-} (A) and Rag1^{-/-} (B) and heterozygote
1280 littermate controls (C57BL/6-background) were pre-treated with streptomycin and
1281 infected with *S.Tm*^{ΔsseD} orally. Fecal *S.Tm* were enriched overnight by culturing a
1282 1:2500 dilution of feces in LB plus kanamycin. These enrichment cultures were then
1283 stained for O:5 and O:12-0 and analysed by flow cytometry (gating as in Fig. S1-4).
1284 The fraction of the population that lost O:5 and O:12-0 antisera staining is shown over
1285 time, as well as the total CFU/g in feces. Both immunocompetent mouse strains show
1286 increased O:5-negative *S.Tm* in the fecal enrichments from day 14 post-infection:
1287 approximately when we expect to see a robust secretory IgA response developing.
1288 These changes are not observed in Rag1-deficient or IgA-deficient mice. The kinetics
1289 of O:5-loss are likely influenced by development or broader IgA responses as the
1290 chronic infection proceeds. *Note that lines joining the points are to permit tracking of*
1291 *individual animals through the data set, and may not be representative of what occurs*
1292 *between the measured time-points.* C. Titres of intestinal lavage IgA specific for O:4[5]
1293 (*S.Tm*^{wt}, O:4[5], 12-0) and O:4(*S.Tm*^{ΔoafA}, O:4,12-0), presented as the dilution of
1294 intestinal lavage required to give an IgA-staining MFI=1000 by bacterial flow
1295 cytometry, and the ratios of these titres. Samples: d28 post-vaccination with PA-STm^{wt}
1296 (n=12) or d35 post-colonization with live-attenuated *S.Tm* (n=8 *S.Tm*^{ΔaroA} + n=8
1297 *S.Tm*^{ΔsseD}), This revealed a weaker, but less biased IgA response in mice infected with
1298 the live-vaccine strain, when compared to that induced by the inactivated oral vaccine.
1299 Results of 2-tailed Mann-Whitney U tests shown.

Fig. S1: Difco Rabbit-polyclonal anti-O:5 and human monoclonal STA5 (specific for O:12-0) can be used to distinguish Salmonella with known O-antigen type, and can be distinguished from contaminants without DNA dyes.

1363

1364 **Fig. S1: Difco Rabbit-polyclonal anti-O:5 and human monoclonal STA5 (specific**
1365 **for O:12-0) can be used to distinguish *Salmonella* with known O-antigen type, and**
1366 **can be distinguished from contaminants without DNA dyes.** Overnight cultures of
1367 the indicated *S. Typhimurium* strains we made in 0.2µm-filtered LB containing
1368 streptomycin (50µg) or Ampicillin (100µg/ml to select for plasmid-maintenance of
1369 pgtrABC-containing strains). 1µl of an OD₆₀₀=2 culture was stained in 0.2µm-filtered
1370 PBS/0.05%Azide with 1:200 Rabbit polyclonal anti-O:5 and 6µg/ml STA5. Brilliant-
1371 violet-421-Donkey-anti-Rabbit (Biolegend) and Alexa-647-anti-human IgG (Jackson
1372 Immunolabs) were used at a 1:200 dilution, and SybrGold at 1:10'000 dilution. Samples
1373 were acquired on a Beckmann Coulter Cytoflex-S. **A.** Full gating is shown for each
1374 sample and the final analysis of O:5 versus O:12-0 staining is shown both for the entire
1375 population gated on Forward- and Side-scatter or only on DNA-dye-positive
1376 *Salmonella*. Note that the live bacteria do not stain uniformly with SybrGold. **B.**
1377 Quantification of the O-antigen variant distribution within each strain, when gating on
1378 the entire population of the SybrGold-positive fraction reveals no difference in the
1379 analysis when DNA dyes are omitted. A sample of LB cultured overnight and treated
1380 as the samples and acquired for the same length of time as the samples (“Media only”)
1381 reveals very little background noise in our flow cytometry analysis. **C.** Schematic
1382 diagram of the O-antigen structures present on bacteria in each quadrant on the scatter
1383 plots.
1384

Primary antibodies

- Polyclonal-anti-O:5 (Rabbit), monoclonal anti-O:12-0 (STA5, human)**
- Polyclonal-anti-O:5 (Rabbit) only**
- monoclonal anti-O:12-0 (STA5, human), only**
- Polyclonal-anti-E.coli O:6 (Rabbit) only (irrelevant specificity)**

Fig. S2: Controls for the specificity of Rabbit-polyclonal-anti-O:5 and STA5 staining.

1385 **Fig. S2: Controls for the specificity of Rabbit-polyclonal-anti-O:5 and STA5**
1386 **staining.** Overnight cultures of the indicated *S. Typhimurium* strains we made in
1387 0.2 μ m-filtered LB containing streptomycin (50 μ g) or Ampicillin (100 μ g/ml to select
1388 for plasmid-maintenance of p μ trABC-containing strains). 1 μ l of an OD₆₀₀=2 culture
1389 was stained in 0.2 μ m-filtered PBS/0.05%Azide with the indicated combinations of
1390 1:200 Rabbit polyclonal anti-O:5, 1:200 Rabbit polyclonal anti-E.coli O:6, 6 μ g/ml
1391 STA5. Brilliant-violet-421-Donkey-anti-Rabbit (Biolegend) and Alexa-647-anti-
1392 human IgG (Jackson Immunolabs) were used at a 1:200 dilution as secondary reagents
1393 in all stainings. Samples were acquired on a Beckmann Coulter Cytoflex-S. **A.** Samples
1394 were gated on Forward- and Side-scatter as in Fig. S1. This reveals good specificity of
1395 the antibodies with the exception of low level cross-reactivity of the anti-human IgG
1396 for the rabbit polyclonal antibody. However, the background generated by this staining
1397 is much lower than the real positive signal and does not alter interpretation of our data.
1398 **B.** Representative histogram overlays of the above stainings indicating antibody
1399 specificity.
1400

A

Fig. S3: Monoclonal antibody STA5 recognises many O:12-containing *S. enterica* O-antigens

1401 **Fig. S3: Characterization of the specificity of STA5 using diverse *Salmonella***
1402 ***enterica* serovars and recombinant *S.Tm* strains. A.** Recombinant monoclonal STA5
1403 human IgG1 was used to surface stain overnight cultures of the indicated *Salmonella*
1404 *enterica* serovars. Bacterial surface binding was detected with a Dylight-647-anti
1405 human IgG secondary antibody and analysed by flow cytometry. STA5 binds to all
1406 serovars that include the O:12 epitope. Top panel shows the pre-gating strategy, which
1407 served only to remove events landing on the axes in forward-scatted and side-scatter
1408 measurements
1409

Fig. S4: Bacterial flow cytometry titring of intestinal IgA, corresponding to Fig, 1F and G

1410

1411 **Fig. S4: Raw data for intestinal IgA titre calculations shown in Fig. 1F and G**
1412 **(binding to *S.Tm* ^{Δ gtrC} (O:4[5],12-0) and *S.Tm* ^{Δ oafA Δ gtrC} (O:4,12-0)).** **A.** Forward- and
1413 side-scatter plot showing gating based on scatter, used for all analysis. **B.**
1414 Representative overlaid histograms of *S.Tm* ^{Δ gtrC} stained with intestinal lavage from a
1415 C57BL/6 mouse orally vaccinated once per week for 4 weeks with PA-STm ^{Δ gtrC} (left)
1416 and PA-STm ^{Δ oafA Δ gtrC} (right). BV421-conjugated anti-mouse IgA was used as a
1417 secondary antibody to reveal IgA coating of *S.Tm*. Colours represent different dilutions
1418 of the intestinal lavages ranging from a dilution factor of 2 (red) to 486 (pink). **C.**
1419 Intestinal lavage dilution factor plotted against the median fluorescence intensity of IgA
1420 staining (circles: PA-STm ^{Δ gtrC}-vaccinated, squares: PA-STm ^{Δ gtrC}-vaccinated) for all
1421 mice shown in Fig. 1F and G. Lines (black = PA-STm ^{Δ gtrC}-vaccinated, orange = PA-
1422 STm ^{Δ oafA Δ gtrC} -vaccinated) indicate 4-parameter logisitic curves fitted to these values
1423 using least-squares non-linear regression. **D.** Titres calculated from the fitted curves as
1424 the intestinal lavage dilution giving a median fluorescence intensity of staining = 1000
1425 for each curve shown in C. Line indicates median value. P value of 2-tailed Mann-
1426 Whitney U test. **E.** Representative overlaid histograms of *S.Tm* ^{Δ oafA Δ gtrC} stained with
1427 intestinal lavage from a mouse orally vaccinated once per week for 4 weeks with PA-
1428 STm ^{Δ gtrC} (left) and PA-STm ^{Δ oafA Δ gtrC} (right). BV421-conjugated anti-mouse IgA was
1429 used as a secondary antibody to reveal IgA coating of *S.Tm*. Colours represent different
1430 dilutions of the intestinal lavages ranging from a dilution factor of 2 (red) to 486 (pink).
1431 **F.** Intestinal lavage dilution factor plotted against the median fluorescence intensity of
1432 IgA staining (circles: PA-STm ^{Δ gtrC}-vaccinated, squares: PA-STm ^{Δ gtrC}-vaccinated) for
1433 all mice shown in Fig. 1F and G. Lines (black = PA-STm ^{Δ gtrC}-vaccinated, orange = PA-
1434 STm ^{Δ oafA Δ gtrC} -vaccinated) indicate 4-parameter logisitic curves fitted to these values
1435 using least-squares non-linear regression. **G.** Titres calculated from the fitted curves as
1436 the intestinal lavage dilution giving a median fluorescence intensity of staining = 1000
1437 for each curve shown in F. Line indicates median value. P value of 2-tailed Mann-
1438 Whitney U test. All vaccinated mice were C57BL/6 and had an SPF microbiota. Note
1439 the significantly higher titres of IgA specific for the vaccination strain than the mis-
1440 matched strain.

1441

1442

Fig. S5: Bacterial flow cytometry titring of intestinal IgA, corresponding to Fig, 1H

1443 **Fig. S5: Raw data for intestinal IgA titre calculations shown in Fig. 1H (binding**
1444 **to $S.Tm^{\Delta oafA, pgrABC}$ (O:4,12-2) and $S.Tm^{\Delta oafA \Delta grC}$ (O:4,12-0).** **A.** Forward- and side-
1445 scatter plot showing gating based on scatter, used for all analysis. **B.** Representative
1446 overlaid histograms of $S.Tm^{\Delta oafA \Delta grC}$ stained with intestinal lavage from a mouse
1447 orally vaccinated once per week for 4 weeks with PA-S $Tm^{\Delta oafA \Delta grC}$. BV421-
1448 conjugated anti-mouse IgA was used as a secondary antibody to reveal IgA coating of
1449 $S.Tm$. Colours represent different dilutions of the intestinal lavages ranging from a
1450 dilution factor of 2 (red) to 486 (pink). **C.** Intestinal lavage dilution factor plotted
1451 against the median fluorescence intensity of IgA staining for all mice shown in Fig. 1H.
1452 Lines indicate 4-parameter logistic curves fitted to these values using least-squares
1453 non-linear regression. **D.** Representative overlaid histograms of $S.Tm^{\Delta oafA pgrABC}$
1454 stained with intestinal lavage from a mouse orally vaccinated once per week for 4 weeks
1455 with PA-S $Tm^{\Delta oafA \Delta grC}$. BV421-conjugated anti-mouse IgA was used as a secondary
1456 antibody to reveal IgA coating of $S.Tm$. Colours represent different dilutions of the
1457 intestinal lavages ranging from a dilution factor of 2 (red) to 486 (pink). **F.** Intestinal
1458 IgA Titres calculated from the fitted curves as the intestinal lavage dilution giving a
1459 median fluorescence intensity of staining = 1000 for each curve shown in E and C.
1460 Lines link the same lavage titred against $S.Tm^{\Delta oafA \Delta grC}$ and $S.Tm^{\Delta oafA pgrABC}$. Red
1461 symbols and lines correspond to samples in which a strain able to phase-vary O:12 out-
1462 completed the O:12-0-locked strain by more than 100-fold on day 4. In each of these
1463 mice, the IgA titre specific for $S.Tm$ with an O:12-0 epitope was higher than the titre
1464 of IgA specific for the phase-varied O:12-2 variant, whereas in mice where the ability
1465 to phase-vary O:12 did not confer a selective advantage, titres against $S.Tm^{\Delta oafA \Delta grC}$
1466 and $S.Tm^{\Delta oafA pgrABC}$ were similar. All vaccinated mice were C57BL/6 and had an SPF
1467 microbiota.
1468
1469

Fig S6: The ΔgrC mutation can be complemented in trans

1470 **Fig. S6: The $\Delta gtrC$ mutation can be complemented in trans:** C57BL/6 mice were
1471 vaccinated and pre-treated as in **Fig. 1**. The inoculum contained a 1:1 ratio of *S.Tm* ^{$\Delta oafA$}
1472 and *S.Tm* ^{$\Delta oafA \Delta gtrC$} *pgtrABC*. Competitive index in feces was determined by differential
1473 selective plating over 4 days post-infection.
1474

Fig. S7: Intestinal Lavage IgA titres from uninfected mice, quantified by ELISA and bacterial flow cytometry

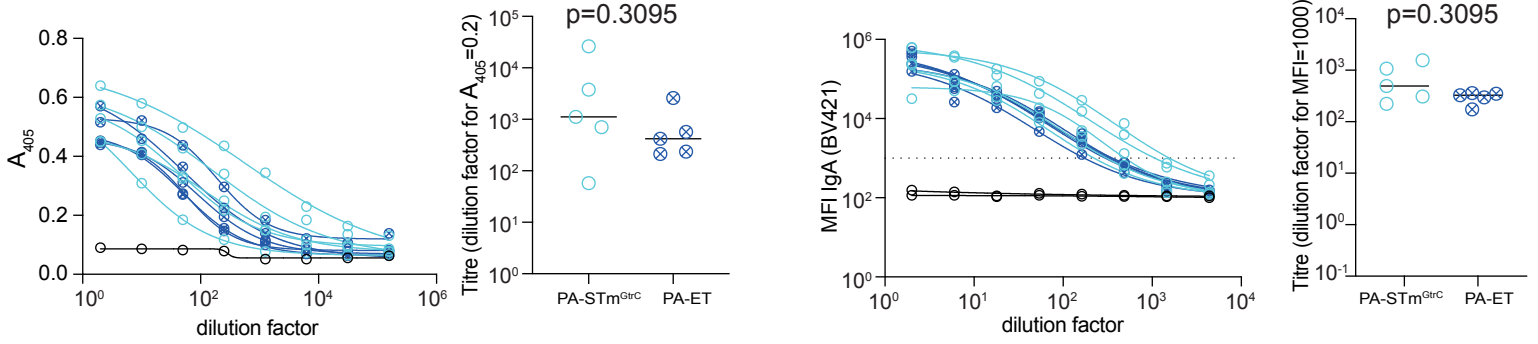

1475 **Fig. S7: Intestinal lavage IgA titre calculations for uninfected C57BL/6 mice**
1476 **vaccinated with PA-STm^{AgtrC} and PA-STm^{ET} by dirty-plate ELISA and flow**
1477 **cytometry.** C57BL/6 mice received either PA-STm^{AgtrC} (n=8) and PA-STm^{ET} (n=11)
1478 per os once per week for 4 weeks. On d28, mice were euthanized and intestinal lavages
1479 collected and cleared by centrifugation. Overnight cultures of *S.Tm^{AgtrC}*, *S.Tm^{pgtrABC}*
1480 *S.Tm^{ΔoafA}* and *S.Tm^{ΔoafA pgtrABC}* were made in 0.2μm-filtered LB containing the relevant
1481 antibiotics. Bacteria were washed twice by centrifugation at 7000g to remove debris
1482 that may have accumulated during growth and used to coat ELISA plates (50μl of
1483 OD=1-0 per well) or as target for bacterial flow cytometry (10⁵ bacteria per sample).
1484 Titration curves plotting A405 (ELISA) or median fluorescence intensity (bacteria flow
1485 cytometry) as read-outs of IgA binding, against dilution factor of lavages were used to
1486 calculate titres from 4-parameter logistic curve-fits. Representative overlaid
1487 histograms of the flow cytometry read-out from one PA-STm^{AgtrC} and PA-STm^{ET}-
1488 vaccinated mouse are shown (Colours represent different 3-fold serial dilutions of the
1489 intestinal lavage: red=2, blue=6, orange=18, green=54, dark green = 162, pink = 486.
1490 Pre-gated on scatted as in Fig. S4). P-values were calculated using 2-tailed Mann
1491 Whitney U tests. Flow cytometry and ELISA reveal similar results, but with flow
1492 cytometry giving a clearer read-out. This is likely due to binding of lysed bacterial
1493 components to the ELISA plate scaffold, including protein components that will be
1494 identical between our strains as well as antigenic, but which are not accessible on the
1495 surface of live cells, and are therefore irrelevant for protection. We have therefore used
1496 bacterial flow cytometry to titre intestinal IgA throughout the manuscript as it more
1497 straightforward to equate to IgA binding to the surface of whole, intact, live cells.

Fig. S8: Intestinal Lavage IgA titres from d9 post-infection, quantified by ELISA and bacterial flow cytometry

1500 **Fig. S8: Intestinal lavage IgA titre calculations for 129S1/SvImJ mice vaccinated**
1501 **with PA-STm^{ΔgrC} and PA-STm^{ET} and infected with *S.Tm*^{WT} for 9 days, by dirty-**
1502 **plate ELISA and flow cytometry.** 129S1/SvImJ mice received the indicated vaccine
1503 per os once per week for 4 weeks. On d28, mice were treated with oral streptomycin
1504 and were infected with *S.Tm*^{WT}. Nine days post-infection, all mice were euthanized and
1505 intestinal lavages collected and cleared by centrifugation. Overnight cultures of
1506 *S.Tm*^{ΔgrC}, *S.Tm*^{pgtrABC}, *S.Tm*^{ΔoafA} and *S.Tm*^{ΔoafA pgtrABC} were made in 0.2μm-filtered LB
1507 containing the relevant antibiotics. Bacteria were washed twice by centrifugation at
1508 7000g to remove debris that may have accumulated during growth and used to coat
1509 ELISA plates (50μl of OD=1-0 per well) or as target for bacterial flow cytometry (10⁵
1510 bacteria per sample). Titration curves plotting A405 (ELISA) or median fluorescence
1511 intensity (bacteria flow cytometry) as read-outs of IgA binding, against dilution factor
1512 of lavages were used to calculate titres from 4-parameter logistic curve-fits. P-values
1513 were calculated using 2-tailed Mann Whitney U tests. Flow cytometry and ELISA
1514 reveal similar results. Note that there is some broadening of the IgA response in PA-
1515 STm^{ΔgrC}-vaccinated mice over the 9 days of infection when compared to the data in
1516 Fig. S7.
1517

Figure S9: IgA-driven selective pressure functions identically in SPF Balb/c mice

1518 **Fig. S9: IgA-driven selective pressure functions identically in SPF Balb/c mice. A-**
1519 **C.** Previous work indicated that Balb/c mice may respond better to oral vaccines and
1520 produce more secretory IgA than C57BL/6 mice (Fransen et al. 2015), therefore we
1521 tested the ability of PA-STm^{ET} to protect in Balb/c mice. Naive (closed circles), PA-
1522 S.Tm^{ΔgtrC}-vaccinated (open circles) and PA-S.Tm^{ET}-vaccinated (crossed-circles) SPF
1523 Balb/c mice were streptomycin-pretreated, infected (10⁵ CFU, 1:1 ratio of S.Tm^{ΔgtrC}
1524 and S.Tm^{ΔgtrC ΔoafA} per os). Note that naïve Balb/c mice were euthanized on day 3 due
1525 to severe disease. **A.** Secretory IgA titres (intestinal lavage dilution) against O:4[5], 12-
1526 0, and an O:4, 12-0 S.Tm. *p=0.0159 **B.** Competitive index (CFU S.Tm^{ΔgtrC}/CFU
1527 S.Tm^{ΔgtrC ΔoafA}) in feces at the indicated time-points. 2-way ANOVA with Bonferroni
1528 post-tests on log-normalized values, compared to naive mice. *p<0.0285. O:4-only
1529 producing S.Tm outcompetes in mice vaccinated with PA-STm^{ΔgtrC} but not PA-STm^{ET}.
1530 **C and D.** Correlation of the competitive index with the O:4-specific (**C**) and O:4[5]-
1531 specific (**D**) intestinal IgA titre, r² values of the linear regression of log-normalized
1532 values. Open circles: Intestinal IgA from PA-S.Tm^{ΔgtrC} -vaccinated mice, crossed
1533 circles: Intestinal IgA from PA-S.Tm^{ET} -vaccinated mice. Lines indicate the best fit
1534 with 95% confidence interval. As both vaccinated groups have similar titres against the
1535 O:4[5]-producing S.Tm, a correlation of C.I. is observed only with the O:4-specific IgA
1536 titre **E.** CFU of S.Tm^{ΔgtrC} (black symbols) and S.Tm^{ΔgtrC ΔoafA} (orange symbols) per
1537 gram feces at the indicated time-points. **F and G.** CFU of S.Tm^{ΔgtrC} (black symbols)
1538 and S.Tm^{ΔgtrC ΔoafA} (orange symbols) per organ and day 4 post-infection (vaccinated)
1539 and day 3 post-infection (naïve). Kruskal-Wallis test with Dunn's multiple comparison
1540 adjusted P values are shown. *p=0.022, **p=0.0085 **H.** Fecal Lipocalin 2 as a marker
1541 of inflammation in the indicated groups. 2-way repeat-measures ANOVA on log-
1542 normalized data, with Bonferroni post-tests comparing to the Naïve mice.
1543 ***p=0.0002, ****p<0.0001 **I and J.** Correlation between fecal lipocalin 2 on d3 post-
1544 infection and O:4 and O:4[5]-specific intestinal IgA titres. r² values of the linear
1545 regression of log-normalized values. Lines indicate the best fit with 95% confidence
1546 interval. *Note that lines joining the points in B, E and H are to permit tracking of*
1547 *individual animals through the data set, and may not be representative of what occurs*
1548 *between the measured time-points.* This experiment was based on the observations
1549 made in Fransen et al⁷² that better IgA-mediated protection is achieved in Balb/c mice
1550 than in C57BL/6 mice in response to live-attenuated vaccines. However, both mouse
1551 lines behave similarly in this model.
1552

Fig. S10. PA-STm^{ET} mediated effects are not improved by addition of S.Tm ^{$\Delta wzyB$} to the vaccine cocktail.

1553

1554 **Fig S10: PA-STm^{ET} mediated effects are not improved by addition of *S.Tm* ^{Δ wzyB}**
1555 **to the vaccine cocktail.** C57BL/6 mice were vaccinated with vehicle only (Naïve,
1556 n=10), PA-*S.Tm*^{wt} (n=8), PA-STm^{ET} (combined PA-*S.Tm* ^{Δ gtrC}, PA-*S.Tm* ^{Δ oafA Δ gtrC}, PA-
1557 *S.Tm* *pgtrABC*, and PA-*S.Tm* ^{Δ oafA} *pgtrABC*, n=9) or PA-STm^{ET+wzyB} (combined PA-
1558 *S.Tm* ^{Δ gtrC}, PA-*S.Tm* ^{Δ oafA Δ gtrC}, PA-*S.Tm* *pgtrABC*, PA-*S.Tm* ^{Δ oafA} *pgtrABC* and PA-
1559 *S.Tm* ^{Δ oafA Δ gtrC Δ wzyB}, n=4). On day 28 after the first vaccination, mice were
1560 streptomycin pre-treated and challenged with 10⁵ *S.Tm*^{wt} orally. Fecal Lipocalin-2
1561 (LCN2) at day 1-3 post-infection, (A) and CFU *S.Tm*^{wt} per gram feces on day 1-3 post
1562 -infection (B), CFU *S.Tm*^{wt} per mesenteric lymph node (MLN) at day 3 post-infection
1563 (C), and CFU *S.Tm*^{wt} per spleen at day 3 post-infection (D). A and B, 2-way repeat-
1564 measures ANOVA on log-normalized data with Bonferroni multiple comparisons-tests
1565 reveals no significant difference between the vaccinated groups at any time-point.
1566 Adjusted p values are displayed. C and D: Kruskal-Wallis analyses **with Dunn's**
1567 **multiple comparisons-tests comparing all groups** were carried out for significance.
1568 Exact adjusted p values displayed. E. IgA titres in intestinal lavage of an experiment
1569 not included in (Fig. 3D), and additionally showing the group PA-*S.Tm* ^{Δ oafA Δ gtrC Δ wzyB}.
1570 Titres are expressed as the dilution factor of lavage required to give an MFI=1000. 2-
1571 way repeat-measures ANOVA on log-normalized data with Bonferroni multiple
1572 comparisons-tests. *Note that lines joining the points in A and B are to permit tracking*
1573 *of individual animals through the data set, and may not be representative of what*
1574 *occurs between the measured time-points.*
