29 **Abstract**

30 How co-transcriptional RNA quality control is regulated remains poorly understood. Here,
 31 we report that in *S. cerevisiae* premature transcription termination of mRNAs is regulated by
 32 the evolutionarily conserved ATP-dependent chromatin remodeling INO80 complex. Loss of
 33 INO80 leads to an increase in promoter-proximally paused RNA Polymerase II and defective
 34 progression into the gene body. We show that promoter-proximal transcriptional pausing
 35 correlates with loading of RNA surveillance and transcription termination factors to mRNA
 36 transcripts. Cells lacking INO80 are defective for the Nrd1-Nab3-Sen1 (NNS)-dependent
 37 pathway for transcription termination at snRNA genes and promoter-proximally sites of
 38 mRNA genes. We demonstrate that INO80 promotes the association of the RNA surveillance
 39 and termination factor Nab2 with short promoter-proximal mRNA transcripts. We provide
 40 evidence that co-transcriptional recruitment of Nab2 to chromatin is regulated by INO80,
 41 which enables the interaction of Nab2 with the histone variant H2A.Z. Our work suggests a
 42 chromatin mechanism for premature transcription termination at promoter-proximally
 43 pausing sites, linking RNA quality control to the transcriptional process.

44 INTRODUCTION

45 Elimination of aberrant mRNAs is essential for proper gene expression. In eukaryotic cells
 46 nuclear RNA surveillance and quality control mechanisms monitor mRNA biogenesis co-
 47 transcriptionally and terminate transcription prematurely for degradation of the nascent RNA
 48 transcript¹. Elegant genome-wide studies in the budding yeast *Saccharomyces cerevisiae*
 49 have suggested that unproductive transcriptional elongation of protein coding genes is wide-
 50 spread and common^{2,3}. Furthermore, promoter-proximal short mRNAs enriched in 3'-
 51 oligo(A) tails have been identified⁴, indicating extensive premature termination across the
 52 yeast protein-coding genome⁵. Likewise, only 10% of promoter-proximally paused
 53 polymerases was shown to enter productive elongation in human cells, with the remaining
 54 being prematurely terminated during abortive elongation^{6,7}.

55 The major nuclear RNA quality control pathway in yeast is mediated by the RNA
 56 surveillance complex Nrd1-Nab3-Sen1 (NNS)⁸ and the Rrp6-dependent nuclear exosome
 57 complex with 3' exonuclease activity⁹. The NNS-dependent nuclear RNA quality control
 58 pathway acts prominently to restrict the extensive and pervasive transcription of non-coding
 59 RNAs (ncRNAs)¹⁰. Nrd1 and Nab3 have also been found to be recruited at active protein-
 60 coding genes with a preference near their 5' end and bind most mRNA transcripts¹¹⁻¹⁵,
 61 suggesting a genome-wide role for NNS in mRNA transcription termination¹⁵ and co-
 62 transcriptional control of mRNA metabolism. However, this model has been challenged by a
 63 separate study, which proposed that only a few mRNA genes are subject to transcriptional
 64 attenuation by the NNS complex¹⁶. Thus, although the RNA surveillance and termination
 65 pathways have been characterized in molecular detail, the mechanisms regulating premature
 66 transcription termination during mRNA synthesis by Pol II remain unclear.

67 In metazoans, short, promoter-associated polyadenylated mRNA transcripts¹⁷ have been
 68 found to associate with Pol II pausing¹⁸, with premature termination and exosome-dependent

69 degradation coinciding with promoter-proximal pausing sites¹⁹. Experiments with chemical
70 transcriptional inhibitors indicated high rates of turnover and premature termination of
71 promoter-proximal paused Pol II^{6,20,21}, suggesting regulation of gene expression by
72 transcriptional attenuation. Even though promoter-proximal pausing plays an important
73 regulatory role in eukaryotic transcription²²⁻²⁵, how pausing is linked to premature
74 termination remains poorly understood.

75 Eukaryotic transcription is controlled by the underlying chromatin structure. ATP-dependent
76 chromatin remodelling enzymes shape the chromatin landscape and act at almost all stages of
77 RNA production controlling transcription activation and silencing, modulation of
78 transcriptional rates, transcription termination and RNA export from the nucleus²⁶⁻³⁰. In
79 mammals, premature termination of mRNA genes and promoter-proximal transcriptional
80 pausing have been associated with nucleosome organization¹⁹. However, the role of
81 chromatin remodelers in co-transcriptional RNA quality control remains elusive.

82 The multisubunit ATP-dependent chromatin remodelling complex INO80 has a well-
83 established and important role in transcription across eukaryotes³¹. INO80 is enriched at the
84 transcription start sites (TSS) of most active and poised mRNA genes in yeast and
85 mammals^{32,33}. The nucleosome remodelling activity of INO80 is important for the exchange
86 of the histone variant H2A.Z for H2A in nucleosomes and for controlling nucleosome
87 positions³¹. While it is generally proposed that the function of INO80 during transcription is
88 to control transcription initiation, INO80 physically interacts with the elongating RNA
89 Polymerase II machinery^{34,35} and binds to mRNAs^{36,37}. This indicates a -yet- undefined role
90 for INO80 in the transcriptional process.

91 Here we investigate the role of INO80 in transcription regulation in *S. cerevisiae*. Using
92 Native Elongating Transcript sequencing (NET-seq) we analyse how the process of
93 transcription is regulated by INO80 at nucleotide resolution. We show that INO80 enables

94 the progression of Pol II from the promoter-proximal region into the gene body. Our analysis
95 indicates that promoter-proximal pausing of Pol II is linked to loading of transcription
96 termination and RNA processing factors to mRNA transcripts. Mechanistically our study
97 reveals that INO80 modulates the interaction between the RNA surveillance and termination
98 factor Nab2 and H2A.Z, enabling recruitment of Nab2 to chromatin. Overall, our results
99 suggest that the chromatin remodelling function of INO80 promotes premature transcription
100 termination.

RESULTS

Defective progression of Pol II from the promoter proximal region into the gene body in the absence of INO80

To illuminate the role of INO80 in transcription, we performed Native Elongating Transcript NET-seq analysis in Wild-Type (WT) and *ino80Δ* yeast cells expressing a FLAG-tag version of the largest subunit of the RNA Polymerase II complex, Rpb1 (Extended Data Fig. 1a, b). NET-seq captures nascent RNAs bound to transcriptionally engaged Pol II and sequences the 3'-end of the purified RNAs, thus providing a detailed map of elongating Pol II across the genome at nucleotide resolution³⁸. Therefore, and to avoid confusion with the term “nascent RNAs” that is commonly used to describe newly synthesized RNAs that are not necessarily associated with Pol II³⁹, we will henceforth refer to the Pol II-associated transcripts captured by NET-seq as Pol II density.

Following removal of duplicated reads and DEseq normalization, NET-seq densities were computed as normalized counts over gene length and their distribution across the gene was compared between the two strains. Consistent with previous reports^{38,40}, promoter-proximal region showed sense Pol II density, with a subsequent reduction further into the gene body in WT cells (Fig. 1a). Interestingly, in *ino80Δ* cells, while sense Pol II density was reduced at the promoter-proximal peak, it decreased further downstream the promoter-proximal region, compared to WT (Fig 1a). Changes in the abundance of sense and antisense NET-seq reads at mRNA genes in *ino80Δ* did not correlate (Extended Data Fig. 1c, $r=0.04$), indicating that altered sense Pol II density in the absence of INO80 is independent of antisense transcription.

We explored whether the decrease in Pol II density downstream the promoter proximal region in *ino80Δ* indicates defective progression of RNA Polymerase II into the gene body. To test this possibility, we calculated Traveling Ratio (TR) values for all mRNA genes by

comparing the Pol II density in the gene body relative to the promoter-proximal region of the first 200bp after the TSS (Fig. 1b). In WT cells, 68% of protein-coding genes exhibited higher Pol II density at the promoter-proximal region compared to Pol II density in the gene body for (TR<1), indicating accumulation of Pol II proximally to promoter for most of the genes. Loss of INO80 led to an overall significant reduction in TR, with 809 genes exhibiting a decrease in TR of at least 1.5 fold-change compared to WT (Fig. 1b). Overall, 73% of genes demonstrated a TR<1 in *ino80Δ*. This indicates a genome-wide defect in progression of Pol II from the promoter-proximal region into the gene body in the absence of INO80.

INO80 physically interacts with the elongating RNA Polymerase II complex^{34,35} and is enriched within gene bodies^{33,41}. To evaluate its role during transcription elongation, we asked whether the enrichment of INO80 inside gene bodies correlates with the intragenic levels of Pol II. ChIP-exo analysis provides near single-nucleotide resolution of factor binding to DNA⁴² and can distinguish between recruitment inside and outside the gene body with great accuracy. When the Ino80⁴¹ and Rpb1 ChIP-exo densities within the gene bodies were compared, a strong, positive correlation between their enrichment was observed (Fig. 1c, r=0.68). This indicates that the presence of INO80 inside the gene is associated with transcription elongation activity.

Chromatin remodelling activity and functionality of the INO80 complex relies on the INO80-specific subunits Arp5 and Arp8³¹. Cells lacking either *INO80* or the INO80-specific subunits *ARP5* or *ARP8* grew poorly in the presence of 6-azauracil (6-AU) (Fig. 1d and Extended Data Fig. 1d, e), an inhibitor of GTP biosynthesis which sensitizes transcriptional elongation mutants⁴³. Therefore, these results suggest that INO80 promotes transcription elongation, supporting a genome-wide, post-initiation role for INO80 in gene expression.

Global downregulation of Pol II transcription in the absence of INO80 is associated with defective mRNA degradation

Increase in transcription initiation can lead to enhanced pausing of Pol II at predetermined sites⁴⁴. We therefore asked whether transcription rates are increased in the absence of INO80, by comparing the levels of newly synthesized mRNAs in WT and *ino80Δ* cells. Cells grown in rich medium were pulse-labelled with 4-thiouracil (4tU) and mixed in a fixed ratio with labelled *S.pombe* cells (spike-in) for normalization⁴⁵. In parallel, 4tU labelling was also conducted in *ino80Δ* cells expressing wild-type *INO80* from a plasmid, serving as a control for *ino80Δ*-mediated changes in RNA expression. Purified total (steady state) and labelled (newly synthesized) RNA from all samples were subjected to sequencing.

After normalization to the *S. pombe* spiked-in signal and applying a cutoff of 1.5-fold change and p-value < 0.05, only 3.6% of all protein coding genes showed significant increase in newly synthesized mRNA levels in *ino80Δ* (n=178, Fig. 3a). Contrary, 34% of the protein-coding genome demonstrated a significant reduction in mRNA synthesis in *ino80Δ* compared to WT (n=1706, Fig. 3a). The downregulation of mRNA synthesis rates was INO80-dependent, since in *ino80Δ* cells expressing *INO80* from an episomal plasmid, less than 4% of genes had markedly decreased newly synthesized mRNA levels (n=193, Extended Data Fig. 3a). Therefore, deletion of INO80 induces genome-wide downregulation of mRNA synthesis rates, arguing against increased transcription initiation as the underlying cause of enhanced Pol II pausing in *ino80Δ*.

Interestingly, despite the global decrease in newly synthesized mRNA levels in *ino80Δ*, the cellular, total mRNA levels for 81% of the protein-coding genes did not significantly change, while 13% were increased in the absence of INO80 (Fig. 3b). This disentanglement between newly synthesized and total RNAs suggests buffering of mRNA transcript levels⁴⁶ in *ino80Δ* by a compensatory mechanism. Cellular mRNA levels are determined by the rates of mRNA synthesis and degradation. To understand why cellular mRNA levels remain high in *ino80Δ*, we conducted comparative dynamic transcriptome analysis (cDTA)⁴⁷, which measures

mRNA synthesis and decay rates (SR and DR respectively) for all protein-coding genes. Comparison of the SR and DR changes in *ino80Δ* relative to WT revealed that the decrease in SR observed in *ino80Δ* positively correlated with a concomitant decrease in DR ($r=0.47$, $p\text{-value}=2.9e^{-233}$, Fig 3c). This indicates that the defect in Pol II transcription in *ino80Δ* is associated with compromised mRNA degradation, in a similar fashion to what has been observed for the *rpb1-N488D* mutant⁴⁷, which reduces the processivity of Pol II⁴⁸.

To verify that mRNAs are stabilized in the absence of INO80, we analysed mRNA decay rates following transcription inhibition with thiolutin in WT and *ino80Δ* cells. Thiolutin was used at concentration below the threshold reported to affect mRNA half-life⁴⁹ and mRNA values were normalized relative to the stable *scR1* RNA, which is transcribed by Pol III. The relative abundance of *NRD1*, *RNAI* and *HPT1* transcripts, which showed decreased DR in the cDTA analysis (Extended data Fig. 3b), was markedly higher in *ino80Δ* compared to WT after transcription inhibition (Fig. 3d and Extended data Fig. 3c). Therefore, the concomitant change in mRNA synthesis and degradation in *ino80Δ* suggest that the transcriptional role of INO80 is linked to RNA decay by buffering steady state mRNA levels.

Promoter-proximal Pol II pausing is linked to increased loading of RNA surveillance and termination factors to mRNA transcripts

The results from our NET-seq and 4tU-seq analysis prompted us to evaluate whether promoter-proximal pausing is linked to nuclear RNA quality control and premature transcription termination.

The nuclear RNA cleavage and termination factor Nab2⁵⁰ and the Trf4/Trf5-Air1/Air2-Mtr4 polyadenylation (TRAMP) complex are required for processing and delivering nascent transcripts to the nuclear exosome for degradation⁵¹⁻⁵⁵. Nab2, Mtr4 and the Nab3 subunit of the NNS complex bind most of mRNAs^{4,56}. We retrieved published genomic data for RNA

binding (CRAC) for Nab3, Nab2 and Mtr4^{4,56}. and corrected their binding to mRNA transcripts for their respective gene transcription levels as measured by CRAC-Rpb1⁵⁶ (Fig. 4a). This normalisation generated an index of Transcript Instability (TI) values for all protein-coding genes, allowing us to quantitatively assess the level of premature transcription termination taking place within each mRNA gene.

We evaluated whether accumulation of Pol II at the promoter-proximal region is associated with premature termination. TI values were calculated for the promoter-proximal region (TSS to TSS+200) and the downstream gene body (TSS+200 to PAS). Genes were clustered in four groups based on their TR values in WT conditions (Fig. 4b) and $TI^{Mtr4/Nab3/Nab2}$ were analysed for the genes of each group. Intriguingly, a reciprocal relationship between TR and promoter-proximal TI was observed: genes with increased accumulation of Pol II at the promoter-proximal region relative to the gene body (low TR) had high $TI^{Mtr4/Nab3/Nab2}$, while genes with little or no promoter-proximal accumulation of Pol II (high TR) had low TI (Fig. 4c). Contrary, no decrease in the $TI^{Mtr4/Nab3/Nab2}$ values was observed within the gene body in the four TR groups (Fig. 4c). Therefore, defective progression of Pol II from the promoter-proximal region correlates with early transcription termination at the same region.

Functional and physical interactions link INO80 to RNA quality control and NNS-dependent transcription termination pathway

Since in *ino80Δ* cells Pol II is stalled at genomic sites associated with increased binding of RNA surveillance factors to RNA, we interrogated whether the role of INO80 in gene expression is functionally linked to the RNA quality control process. Abd1 is an essential m7G cap methyltransferase that prevents mRNA destabilization and degradation⁵⁷. Deletion of *ARP8* in the *abd1-DAmP* strain, which expresses a hypomorphic allele of *ABD1*⁵⁸, led to synthetic lethality in non-permissive conditions (Fig. 5a), suggesting that INO80 is essential for cellular viability when mRNAs are destabilized. Deletion of *ARP8* in the *nr1-V368G*

(designated as *nrd1-5*) mutant strain, which is deficient in transcription termination⁸ led to synthetic lethality in 6-AU (Fig. 5b). In addition, the *arp8Δ* and *nrd1-5* mutants were epistatic for *INO1* expression (Fig. 5c) suggesting that the INO80 and NNS complexes work in the same pathway in gene regulation. These genetic interactions link INO80 to co-transcriptional RNA quality control, prompting us to test whether the INO80 complex physically associates with the transcription termination machinery.

Protein co-immunoprecipitation analysis after nucleic acid removal demonstrated that the INO80 complex physically interacts with both Nrd1 and Nab2 *in vivo* (Fig. 5d, e). Contrary, we could not detect a physical interaction between the INO80 complex and the component of cleavage and polyadenylation factor IA (CF IA) complex Pcf11 (Extended Data Fig. 4a), which promotes transcription termination at the PAS.

INO80 promotes NNS-dependent transcription termination

To explore the possibility that INO80 is involved in Nrd1-dependent termination, we employed the well-characterized *ACT-SNR^{TTS}-CUP* reporter system^{8,59} (Extended Data Fig. 5a). Briefly, cells were transformed with ACT-CUP plasmids without or with the Transcription Termination Site (TTS) of the snoRNA gene *SNR13* (*SNR^{TTS}*) inserted prior to the CUP1 gene, which confers resistance to copper. Termination of snoRNAs, including *SNR13*, is regulated by the NNS complex^{8,60}. INO80 is co-enriched with Nrd1 at the endogenous *SNR13^{TTS}* region (Extended Data Fig. 4b), making the *ACT-SNR^{TTS}-CUP* reporter a suitable system to test the role of INO80 in NNS-dependent transcription termination. Contrary to WT, *ino80Δ* cells transformed with the *ACT-SNR^{TTS}-CUP* plasmid were able to grow in the presence of copper, suggesting read-through transcription of *CUP1* (Fig. 6a). RT-qPCR analysis using primer pairs that target the regions before and after the *SNR13^{TTS}* insertion site in the reporter plasmids showed a significant increase in the relative transcription of *CUP1* in the *ACT-SNR^{TTS}-CUP* plasmid in *ino80Δ* and *arp8Δ* mutants by 2.8-

fold and 3.5-fold respectively (Fig. 6b and Extended Data Fig. 5c). Similarly, a 3-fold increase was observed in *nrd1-5* cells, in accordance to previous studies⁸ (Fig. 6b and Extended Data Fig. 5c). Inducible degradation of Ino80 also resulted in an acute increase in relative *CUP1* levels from the *ACT-SNR^{TTS}-CUP* but not from the control *ACT-CUP* plasmid lacking the transcription termination site (Extended Data Fig. 5d). Deletion of either *INO80* or *ARP8* did not significantly alter gene expression of any of the known transcription termination and RNA surveillance factors (Extended Data Table 2). These results support a direct role for INO80 in transcription termination at the *SNR13^{TTS}* termination site.

To further substantiate a role for INO80 in NNS-dependent termination, we evaluated read-through transcription at the termination sites of endogenous snoRNA genes. Using paired-end, spiked-in RNA sequencing we mapped the sense RNA-seq reads encompassing the TTS of the snoRNA genes in WT and *ino80Δ*. In the absence of INO80 read-through transcripts are significantly increased for the majority of the snoRNA genes, but not for the ribosomal protein coding gene *YNL096C* (Fig. 6c, d, and Extended Data Fig. 5e and Extended Data Table 3). The increase in readthrough transcripts in *ino80Δ* is not due to defective degradation, as termination of snoRNAs in cells deleted for the 5'-3' exoribonuclease *XRN1* was normal, while deletion of the nuclear exosome subunit *RRP6* compromised termination only at a small number of specific snoRNA genes, in accordance with previous studies^{61,62} (Fig. 6d and Extended Data Table 2). These results suggest that INO80 promotes NNS-dependent transcription termination.

To investigate the effect of INO80 loss on premature termination of mRNA synthesis, we focused our analysis on the *NRD1* gene, which is a known target for promoter-proximal transcription termination by the NNS/Rrp6 pathway^{8,61}. Ino80 is enriched at the promoter-proximal region of *NRD1* (Extended Data Fig. 5f) and loss of INO80 resulted in increased promoter-proximal Pol II density at *NRD1* compared to WT (Extended Data Fig. 5g). To

assess termination proximally to promoters and at the end of the gene we conducted quantitative 3' rapid amplification of cDNA ends (3' RACE) using gene-specific primers for either the promoter-proximal or the PAS region of the *NRD1* gene respectively. Deletion of *RRP6* increased the relative abundance of promoter-proximally terminated *NRD1* mRNAs compared to WT, while also upregulated the expression of *NRD1* transcripts terminated at the end of the gene, in line with RNA-seq data (Fig. 6e and Extended Data Fig. 5h). Notably, deletion of either *INO80* or *APR8* attenuated the expression of early terminated transcripts compared to the PAS-terminated *NRD1* transcripts (Fig. 6e). This suggests that the INO80 complex promotes premature transcription termination at mRNA genes.

INO80 promotes chromatin recruitment and association of Nab2 with H2A.Z

To understand the mechanism underlying the function of INO80 in premature termination, we hypothesized that INO80 regulates the recruitment of the RNA quality control machinery to chromatin. The RNA surveillance factor Nab2 promotes transcription termination⁵⁰. Nab2 binds promoter-proximal mRNAs that are prematurely terminated⁴, including *NRD1* (Extended Data Fig. 6a), while it is co-transcriptionally recruited to the gene body of actively transcribed mRNA genes¹². We therefore tested by ChIP-qPCR whether association of Nab2 with chromatin depends on INO80. Co-transcriptional recruitment of Nab2 to the promoter-proximal region of *NRD1* was reduced in the absence of INO80 (Fig. 7a and Extended Data Fig. 6b). Likewise, Nab2 co-transcriptional recruitment at the *SNR13* gene was also compromised in *ino80Δ* (Extended Data Fig. 6c). Co-immunoprecipitation for Nab2 confirmed that the physical interaction between Nab2 and Rpb1 was independent of INO80 (Extended Data Fig. 6d), excluding the possibility that the decreased recruitment of Nab2 to chromatin is caused by compromised binding to the Pol II machinery. To evaluate whether loss of INO80 disrupts the association of Nab2 with the promoter-proximal *NRD1* transcript, we conducted quantitative RNA-IP for Nab2. In *ino80Δ* cells the binding of Nab2 to

promoter-proximal *NRDI* RNA was significantly reduced compared to its binding to the PAS-proximal *NRDI* region (3'-*NRDI*) (Fig. 7b). These results suggest that INO80 regulates recruitment of Nab2 to chromatin to promote its binding to nascent RNAs.

We sought to gain insight into how INO80 promotes recruitment of Nab2 to chromatin. Promoter-proximal nucleosomes are enriched in the histone variant H2A.Z⁶³. H2A.Z has been suggested to have a role in RNA quality control and non-PAS transcription termination in *D.melanogaster* and *S.pombe*⁶⁴⁻⁶⁶. INO80 preferentially remodels nucleosomes containing H2A.Z and controls the dynamic association of H2A.Z with chromatin^{33,67-69}, raising the possibility that H2A.Z might be involved in NNS-dependent termination. Cells lacking *HTZ1*, which encodes for H2A.Z in budding yeast, grew in the presence of copper when transformed with the *ACT-SNR^{TTS}-CUP* plasmid (Fig.7c and Extended Data Fig. 6f), suggesting that H2A.Z suppresses read-through transcription from NNS-dependent termination sites. Promoter-proximally terminated *NRDI* transcripts were decreased in *htz1Δ* compared to WT (Fig. 7d), indicating that loss of H2A.Z compromises premature transcription termination of mRNA genes. In line with defective early termination, co-transcriptional recruitment of Nab2 at the promoter-proximal region of *NRDI* was reduced in *htz1Δ* cells (Fig. 7e and Extended Data Fig. 6g). Co-immunoprecipitation assays after nucleic acid removal demonstrated that H2A.Z interacts with Nab2, even after non-physiological high-salt wash conditions, but not with Pcf11 (Fig. 7f and Extended Data Fig. 7h, i). Since our evidence indicate that H2A.Z is involved in premature transcription termination and RNA quality control at mRNA genes, we asked whether INO80 controls the interaction between H2A.Z and Nab2. Remarkably, binding of Nab2 to H2A.Z was decreased in *ino80Δ* (Fig. 7f). This suggests that INO80 enables the recruitment of the Nab2 RNA surveillance machinery to chromatin by promoting its interaction with H2A.Z.

DISCUSSION

Here, we elucidate a role for INO80 in transcription. We report that INO80 enables recruitment of the RNA quality control machinery to transcribed mRNA genes for early transcription termination, promoting transcription elongation. Our data suggest that by removal of Pol II and termination of unproductive transcription, INO80 defines a chromatin-based pathway for co-transcriptional mRNA quality control. Based on our results we propose that control of premature transcriptional termination by INO80-dependent chromatin remodelling is a genome-wide regulatory mechanism of eukaryotic gene expression.

Linking mRNA quality control to chromatin regulation

What is the role of Pol II accumulation at the promoter-proximal region? Our analysis links promoter-proximal accumulation of Pol II with RNA surveillance and transcription termination. Binding of the RNA quality control factors Nab3, Mtr4 and Nab2 to mRNA transcripts is enhanced at promoter-proximal regions. Therefore, a model emerges that increased dwelling of Pol II at specific promoter-proximal sites provides the time for RNA surveillance and termination factors to be loaded to nascent transcripts efficiently. Our cumulative findings that in the absence of INO80 (i) Pol II accumulates at promoter proximal regions, (ii) Nab2 recruitment to chromatin and binding to RNA are defective and (iii) early termination is compromised, suggest that removal of Pol II molecules that are not engaged in productive transcription is mediated by INO80. Given that loss of INO80 results in reduced transcription rates, our results substantiate the hypothesis that chromatin promotes transcription by orchestrating the co-transcriptional RNA quality control pathway. It is therefore tempting to speculate that chromatin acts as a molecular switch that dictates whether Pol II will either progress into productive elongation or be removed to allow for the next round of transcription to take place.

Chromatin regulation of premature transcription termination by INO80

How does INO80 promote premature termination? The physical interactions of the INO80 complex with the transcription termination and RNA surveillance factors Nrd1 and Nab2, and the enrichment of INO80 at NNS-dependent termination regions suggest a direct involvement for INO80 in the co-transcriptional RNA quality control pathway. Nab2 associates with the RNA cleavage factor Hrp1⁷⁰ and both factors are involved in mRNA quality control and NNS-dependent termination^{4,71,72}. The INO80-dependent recruitment of Nab2 to chromatin could therefore promote co-transcriptional cleavage of the nascent RNA, leading to destabilization of the transcription elongation complex and subsequent release of Pol II from chromatin. As INO80 interacts with and facilitates release of poly-ubiquitinated Rpb1 from chromatin³⁵, an intriguing possibility is that Rpb1 ubiquitination is involved in the process, providing specificity for selective eviction of Pol II molecules by INO80.

In agreement with a role for H2A.Z in RNA quality control and non-poly(A) transcription termination⁶⁴⁻⁶⁶, our results suggest that INO80 promotes recruitment of Nab2 to chromatin by regulating its interaction with H2A.Z (Figure 7). This implies that remodelling of H2A.Z-containing nucleosomes by INO80⁶⁷⁻⁶⁹ is important for premature termination. It is therefore likely that intermediate steps in the H2A.Z exchange reaction by INO80, for example disposing of DNA from the surface of H2A.Z-H2B dimers⁶⁹, might be involved in the process. How H2A.Z promotes recruitment of the RNA quality control machinery to chromatin is not clear. It would not be surprising if regulation of premature termination entails posttranslational modifications on H2A.Z, which would command its role in the RNA quality control pathway.

Promoter-proximal transcriptional pausing has recently been linked to premature termination in metazoans^{6,19-21}. Uncontrolled transcription elongation and dysregulated Pol II pausing have been implicated in human disease^{73,74}. Mutations in the RNA surveillance machinery have been associated with increased transcriptional stress and genomic instability⁷⁵, both

373 hallmarks of cancer⁷⁶. Dysregulated expression of INO80 leads to uncontrolled gene
374 expression and is associated with disease^{31,77,78}. We therefore anticipated that our reported
375 chromatin mechanism of co-transcriptional RNA quality control has general relevance for
376 regulation of eukaryotic gene expression and in disease.

Figure 1

Fig. 1. Accumulation of nascent mRNA transcripts on chromatin proximally to promoters and defective transcriptional elongation in the absence of INO80.

a, Metagene analysis for NET-seq density profiles averaged across scaled mRNA genes (n=5432) in WT and *ino80Δ*. Tags were aligned to both Transcription Start Site (TSS) and Polyadenylation Site (PAS) for each gene. n=2. **b**, Top: Schematic representation and formula for calculating the Traveling Ratio (TR) from NET-seq mRNA densities. Bottom: Cumulative distribution plot of Traveling Ratio for mRNA genes from a (n=5432). Genes with TR>2 (WT: n=354, *ino80Δ*: n=314) are not shown. ****p < 0.0XXX with K-S test. **c**, Scatterplot analysis comparing Ino80³³ and Rpb1 ChIP-exo densities between the transcription start site and polyadenylation site (TSS to PAS) in mRNA yeast genes (n=5798). Pearson's correlation coefficient (r) and p-value are indicated. **d**, Cell proliferation

610 analysis for WT and *ino80Δ* strains grown exponentially in SC-ura and in SC-ura containing
611 50 µg/ml 6-azauracil (6-AU) liquid media for the indicated time. Cell density was measured
612 at OD⁶²⁰ and plotted on a log₂ scale. Doubling time was calculated from OD⁶²⁰: 0.2 to OD⁶²⁰:
613 0.4 for all strains in both conditions. Fold Change ratio (FC) of doubling time in 6-AU over
614 SC-ura for each strain is shown. n=4.

Figure 3

Fig. 3. mRNA synthesis and decay rates are reduced in the absence of INO80.

a, b, Scatterplot analysis for fold changes between WT and *ino80Δ* in newly synthesized mRNA (a) and steady-state mRNA (b) levels (n=5012 genes) plotted on a log₂ scale. Thresholds of 1.5-fold change and 0.05 p values were considered for significant change (green dots). n=3. **c**, cDTA profiles for *ino80Δ*. For all analysed genes, changes in synthesis rates (SR) were plotted against the changes in mRNA decay rates (DR). Fold-change in SR and DR were calculated between *ino80Δ* and WT and plotted on a log₂ scale. 90% of genes are contained within the outer contour. Yellow and red dots correspond to 60% of genes. **d**, RT-qPCR analysis for *NRD1* and *RNA1* RNAs was conducted in WT and *ino80Δ* before (T₀) and after addition of thiolutin in YPD. RNA abundance at each time-point was normalized

over the respective abundance of the *SCR1* RNA. RNA before thiolutin treatment was set at 100% in both strains. Remaining RNA was calculated as the amount of normalized RNA in the indicated time-points relative to the normalized RNA at T_0 . Values represent the average from at least three independent experiments. Bars, standard errors.

Figure 4

Fig. 4. Loading of the RNA surveillance and termination factors Mtr4, Nab3 and Nab2 on promoter-proximal mRNA transcripts.

a, Formula for calculating Transcript Instability (TI) as the ratio of the averaged CRAC densities of Nab3⁵⁶, Mtr4 or Nab2⁴ to CRAC densities of Rpb1⁵⁶ for mRNA genes. **b**, Schematic table for clustering mRNA genes according to the relative TR in WT (TR^{WT}). The number of genes and the level of promoter-proximal pausing are indicated for each cluster. **c**, Boxplot analysis comparing TIs calculated for the promoter-proximal and gene body regions of mRNA genes in the four clusters defined by their relative TR^{WT}. p-values were calculated by Wilcoxon rank-sum test. ****, p<0.0001. ***, p<0.001. **, p<0.01. ns, non-significant.

Figure 5

Fig. 5. Genetic and physical interactions of INO80 with the RNA quality control pathway.

a, 5-fold serial dilution of exponentially grown cells from the indicated strains were plated onto YPD and incubated at 30°C (permissive temperature) or 37°C (non-permissive temperature) for 4-5 days. **b**, 5-fold serial dilution of exponentially grown cells from the indicated strains were plated onto both SC-ura and SC-ura + 50μg/ml 6-Azauracil (6-AU) and incubated at 30°C for 4-5 days. **c**, RT-qPCR analysis for *INO1* RNA was conducted in the indicated strains grown exponentially in SC media (0h) or SC without inositol for 14h. *INO1* RNA was normalized over *ACT1* RNA. Bars, standard errors (n=3). Asterisks indicate statistical significance of the indicated change as calculated by Tukey's multiple comparisons test. ns: non-significant. **d**, Nucleic acid-free lysates from cells co-expressing Nrd1-HA with Ino80 either untagged or tagged with FLAG epitope were subjected to FLAG-IP. Inputs and IP samples were immunoblotted for FLAG, Arp5, HA. Immunoblot against Pgk1 served as a control. **e**, Nucleic acid-free lysates from cells expressing Nab2-HA were subjected to either

656 HA-IP (Nab2-HA) or IgG-IP (mock). Inputs and IP samples were immunoblotted for Arp5
657 and HA.

Figure 6

Fig. 6. NNS-dependent transcriptional termination is defective in *ino80Δ*.

a, 5-fold serial dilution of cells from the indicated strains were plated onto both SC-leu and SC-leu + 0.25mM CuSO₄ and incubated at 30°C for 3 (SC-leu) and 7 days (CuSO₄). **b**, RT-qPCR analysis was conducted in WT, *nrd1-5*, *arp8Δ* and *ino80Δ* cells transformed with either *ACT-CUP* or *ACT-SNR^{TTS}-CUP* plasmids. The *CUP1/ACT** ratio from the *ACT-SNR^{TTS}-CUP* plasmid was normalized over the same ratio from the control *ACT-CUP*

665 plasmid (Extended Fig. 4c) to correct for differential transcription across all strains. Read-
666 through at the *SNR13*^{TTS} for each indicated strain is shown as Fold Change Ratio over WT.
667 Bars, standard errors from three independent experiments. p-values were calculated by t-test
668 after testing for normal distribution by Shapiro-Wilk test. *, p<0.05. **, p<0.01. **c**, Snapshot
669 of RNA-seq densities in WT and *ino80Δ* across the *SNR47* snoRNA gene. Solid lines, density
670 of reads encompassing the transcription termination site (5'-TTS-3') of the *SNR47* gene.
671 Broken lines, total RNA-seq density. Reads encompassing the TTS were selected from the
672 total RNA-seq reads as containing 5' upstream the *SNR47* TTS and 3' at or after the *SNR47*
673 TTS. Genomic coordinates of Chromosome IV around the *SNR47* gene (coordinates: 541700
674 to 541602) are shown. The closest downstream gene is *YDR042C* (TSS: Chromosome IV,
675 541203). n=4. **d**, Upper panel, formula for calculating the Read-through Index (RI) from
676 RNA-seq densities across snoRNA genes that encompass transcription termination sites (5'-
677 TTS-3'). RNA-seq reads with 5' upstream the TTS and 3' at or after the TTS were selected
678 from the total RNA-seq read pool and the ratio of the RNA-seq read density after TTS to the
679 RNA-seq read density before TTS in the selected reads was calculated. Lower panel, boxplot
680 analysis comparing RI from the indicated strains across snoRNA genes. p-values were
681 calculated by Wilcoxon matched-pairs rank test after testing for normal distribution. ****,
682 p<0.0001. *, p<0.05. ns, non-significant. **e**, Top: Scheme illustrating nested 3'RACE for
683 termination events at the promoter-proximal (5') and PAS (3') regions of the *NRD1* gene
684 (*NRD1* 5', dark blue). Bottom: 3'RACE analysis for *NRD1* termination events was conducted
685 in WT and the indicated mutant strains. The relative enrichment of polyadenylated promoter-
686 proximal to PAS-terminated transcripts (5'/3') was calculated for all strains and the fold
687 change in each mutant compared to WT was plotted on a log₂ scale. n=3. p-values were
688 calculated by t-test after testing for normal distribution by Shapiro-Wilk test. *, p<0.05.

Figure 7

Fig. 7. INO80 promotes the co-transcriptional recruitment of Nab2 to chromatin and its association with H2A.Z.

a, Chromatin immunoprecipitation for Nab2-HA and Rpb1 in WT and *ino80Δ* cells. Fold enrichment of each protein at the promoter-proximal region of *NRD1* gene (*NRD1* 5') (upper panel, shaded in dark blue) was calculated relative to the *GAL1* promoter after correction for input DNA levels. ChIP ratio at the promoter-proximal region of *NRD1* gene (*NRD1* 5') was calculated as Fold enrichment of Nab2-HA over Fold enrichment of Rpb1. Bars, standard

errors from four independent experiments. p-values were calculated by t-test after testing for normal distribution by Shapiro-Wilk test. *, $p < 0.05$. **b**, RNA immunoprecipitation for Nab2-HA in WT and *ino80Δ* cells. Ratio of binding of Nab2 to the promoter-proximal *NRD1* RNA (upper panel, *NRD1* 5', dark blue) over binding to the 3' region of *NRD1* RNA (upper panel, *NRD1* 3', light blue) after correction for input (total) RNA levels in the indicated strains. Bars, standard errors from four independent experiments. p-values were calculated by t-test after testing for normal distribution by Shapiro-Wilk test. ***, $p < 0.001$. **c**, Cell proliferation analysis for the indicated strains transformed with the *ACT-SNR^{TTS}-CUP* plasmid grown exponentially in SC-ura (left panel) and in SC-ura liquid media containing 0.4mM CuSO₄ (6-AU) (right panel) for the indicated time. Cell density was measured at OD⁶²⁰ and is shown on a log₂ scale. **d**, Nested 3'RACE analysis for termination events at the *NRD1* gene was conducted in WT and *htz1Δ*. Analysis was conducted as in Fig. 6e. n=4. p-values were calculated by t-test after testing for normal distribution by Shapiro-Wilk test. **, $p < 0.01$. **e**, Chromatin immunoprecipitation for Nab2-HA and Rpb1 in WT and *htz1Δ* cells. Analysis was conducted as in (a). Bars, standard errors from three independent experiments. p-values were calculated by t-test after testing for normal distribution by Shapiro-Wilk test. **, $p < 0.01$. **f**, Representative H2A.Z immunoprecipitation experiment. Nucleic acid-free lysates from WT and *ino80Δ* cells expressing Nab2-HA were subjected to H2A.Z-IP. Inputs and IP samples were immunoblotted for H2A.Z and HA. Nab2-HA enrichment in H2A.Z pulldowns is calculated as HA/H2A.Z IP ratio, corrected for the relative Nab2-HA abundance in the input samples. Nab2-HA enrichment in WT is set arbitrarily to 1.0. All analysis was conducted from the same SDS-page gel.

Extended Data Fig. 1

Extended Data Fig. 1. NET-seq and 6-AU cell growth analysis in the absence of INO80.

a, Heatmap of Pearson's correlation coefficients (R) for all pairwise combinations of NET-seq reads in independent biological replicates. **b**, Rpb1-FLAG is efficiently immunoprecipitated from yeast cells during NET-seq analysis. Lysates from WT and *ino80Δ* cells expressing *RPB1-FLAG* were subjected to FLAG immunoprecipitation using FLAG beads. Rpb1-FLAG was subsequently eluted from the beads with FLAG peptide. Input,

eluate and unbound samples were immunoblotted against FLAG epitope and total Rpb1. Immunoblotting against Pgk1 serves as loading control. All samples were resolved in the same SDS-page gel. **c**, Scatterplot analysis comparing the changes in NET-seq densities between WT and *ino80Δ* for sense transcripts and their relative antisense transcripts over mRNA gene regions, plotted on a log₂ scale. Pearson's correlation coefficient (r) is indicated. **d**, Cell proliferation analysis for the indicated strains grown exponentially in SC-ura (top panel) and in SC-ura containing 50μg/ml 6-azauracil (6-AU) (bottom panel) liquid media for the indicated time. Cell density was measured at OD⁶²⁰ and shown on a log₂ scale. Shading surrounding each line denotes standard error from four independent experiments. The mutant strain deleted for the RNA Polymerase II subunit Rpb9 (*rpb9Δ*) has reported transcriptional elongation defects in 6-AU⁷⁹ and was used as control. Doubling time from OD⁶²⁰ 0.2 to OD⁶²⁰ 0.4 was calculated for all strains in both conditions. Fold Change ratio (FC) of doubling time in 6-AU over SC-ura is shown (bottom panel). **e**, 5-fold serial dilution of cells from the indicated strains were plated onto both SC-ura and SC-ura + 50μg/ml 6-Azaauracil (6-AU) and incubated at 30°C for 4-5 days. Genetic backgrounds (LS20, W303) are indicated. The mutant strain deleted for the Dst1/TFIIS transcription elongation factor (*dst1Δ*) was used as control⁸⁰.

Extended Data Fig. 3. Ectopic expression of INO80 rescues the nascent mRNA synthesis defect of *ino80Δ* cells.

a, Scatterplot analysis for fold changes in newly synthesized mRNA between *ino80Δ* cells expressing a WT allele of *INO80* from the pRS416 plasmid (*pINO80*) and WT cells transformed with the empty vector pRS416 (EV) plotted on a log₂ scale. Analysis as in Fig.3a. **b**, Fold changes in mRNA decay rates between *ino80Δ* and WT for the indicated genes as calculated by cDTA analysis. **c**, RT-qPCR analysis for *HPT1* RNA was conducted in WT and *ino80Δ* before (T₀) and after addition of thiolutin in YPD as in Fig. 3d.

Extended Data Fig.4

754

755 **Extended Data Fig. 4. INO80 does not interact with Pcf11.**

756 **a**, Nucleic acid-free lysates from cells co-expressing Pcf11-HA with Ino80 either untagged or
 757 tagged with FLAG epitope were subjected to FLAG-IP. Inputs and IP samples were
 758 immunoblotted for FLAG, Arp5 and HA. Samples were resolved in the same SDS-page gel.

Extended Data Fig.5

759

760

Extended Data Fig. 5. Defective NNS-dependent transcription termination in *ino80Δ* cells.

a, Schematic representation of the *ACT-CUP* (pGAC24) and *ACT-SNR^{TTS}-CUP* (pGAC24-SNR13^{TTS}) reporter systems for transcription termination reported in⁸. The regions amplified by RT-qPCR for *ACT** and *CUP1* are underlined. The region of the *SNR13* gene between +125 to +232bp from TSS that was cloned in the *ACT-SNR13^{TTS}-CUP* plasmid⁸ is shaded in blue (*SNR13**). The expected phenotype of cells transformed with either the *ACT-CUP* or the *ACT-SNR13^{TTS}-CUP* plasmid is shown. **b**, Snapshot of Nrd1 PAR-CLIP density profile from⁸¹ and Ino80 ChIP-exo density profile from³³ across the *SNR13* snoRNA gene. Tags were aligned relative to TSS and plotted on a log₂ scale. The region between +125 to +232bp from TSS cloned in the *ACT-SNR13^{TTS}-CUP* plasmid described in (a)⁸ is highlighted in blue (*SNR13**). **c**, RT-qPCR analysis for the *CUP1/ACT** ratio was conducted in the indicated strains transformed with either the *ACT-CUP* (left panel) or *ACT-SNR^{TTS}-CUP* (right panel) plasmids. Bars, standard errors from three independent experiments. Asterisks indicate statistical significance of the change in the respective mutant compared to the WT as calculated by t-test. ns: non-significant. *, p<0.05. ***, p<0.001. **d**, RT-qPCR analysis was conducted in both WT and the *ino80-td* degenon-inducible strain (*ino80-td*)⁸² transformed with the *ACT-CUP* control plasmid described in a. Galactose-induced activation for 3 hours at 37°C (+) and glucose-induced suppression (–) of the *UBR1* N-recogin in the two strains is indicated. Bars, standard errors from four independent experiments. p-values were calculated by t-test after testing for normal distribution by Shapiro-Wilk test. ns, non-significant. **e**, Snapshot representing RNA-seq densities in WT and *ino80Δ* across the ribosomal protein coding gene YNL096C. Solid lines, density of reads encompassing the transcription termination site (5'-TTS-3') as described in Fig. 6c. Analysis was performed around the polyadenylation site (PAS). Broken lines, total RNA-seq density. Genomic coordinates of

786 Chromosome XVI around the *YNL096C* gene are shown. The closest gene downstream of
 787 *YNL096C* is the *PHO23* mRNA gene (TSS: Chromosome XIV, 442509). **f**, Snapshot
 788 representing ChIP-exo densities of Ino80 from ⁴¹ across the *NRD1* gene. **g**, Snapshot
 789 representing NET-seq densities in WT and *ino80Δ* across the *NRD1* gene. **h**, Representative
 790 image of nested 3'RACE analysis of termination events at the *NRD1* 5' and 3' regions
 791 according to the scheme in Figure 6e and at the 3' of *ACT1* gene in WT and *rrp6Δ* on an
 792 agarose gel. Boxes indicate the most frequent termination sites. Ladder is 100bp. *ACT1*
 793 serves as loading control.

Extended Data Fig. 6

Extended Data Fig. 6. Co-transcriptional recruitment of Nab2 to chromatin depends on INO80 and H2A.Z.

a, Snapshot representing CRAC densities for Nab2 from ⁴ across the *NRD1* gene. **b**, Chromatin immunoprecipitation for Rpb1 and Nab2-HA in WT and *ino80Δ* cells. Fold

799 enrichment analysis at the promoter-proximal region of *NRD1* gene (*NRD1* 5') (upper panel,
800 shaded in dark blue) was conducted as Fig. 7a. **c**, Chromatin immunoprecipitation for Nab2-
801 HA and Rpb1 in WT and *ino80Δ* cells. Fold enrichment of each protein at the TTS region of
802 *SNR13* gene was calculated relative to the *GALI* promoter after correction for input DNA
803 levels. ChIP ratio at the TTS region of *SNR13* gene was calculated as Fold enrichment of
804 Nab2-HA over Fold enrichment of Rpb1. Bars, standard errors from four independent
805 experiments. p-values were calculated by t-test after testing for normal distribution by
806 Shapiro-Wilk test. *, p<0.05. **d**, Nucleic acid-free lysates from WT and *ino80Δ* cells both
807 expressing Nab2-HA were subjected to HA-IP. Inputs and IP samples were immunoblotted
808 for Rpb1 and HA. Mock, WT protein lysate subjected to immunoprecipitation with a control
809 IgG antibody. **e**, Metagene analysis for ChIP-exo density profiles of histone H3 in WT and
810 *ino80Δ* aligned at the A nucleotide of the ATG sites in the TSS to TSS+200bp (Promoter-
811 proximal) and the TSS+200 to PAS (Gene body) regions. n=Number of ATG sites in each
812 region. **f**, Cell proliferation analysis for the indicated strains transformed with the *ACT-CUP*
813 plasmid grown exponentially in SC-ura (left panel) and in SC-ura liquid media containing
814 0.4mM CuSO₄ (6-AU) (right panel) for the indicated time. Cell density was measured at
815 OD⁶²⁰ and is shown on a log₂ scale. **g**, Chromatin immunoprecipitation for Rpb1 and Nab2-
816 HA in WT and *htz1Δ* cells. Fold enrichment analysis at the promoter-proximal region of
817 *NRD1* gene (*NRD1* 5') was conducted as Fig. 7a. **h**, Nucleic acid-free lysates from WT cells
818 expressing Nab2-HA were subjected to immunoprecipitation with either an anti-H2A.Z
819 antibody (+) or a non-specific IgG antibody as a control (-), then washed in the presence of
820 300mM NaCl. Inputs and IP samples were immunoblotted for HA and H2A.Z. All analysis
821 was conducted from the same SDS-page gel. **i**, Nucleic acid-free lysates from cells
822 expressing Pcf11-HA were subjected to immunoprecipitation with either an anti-H2A.Z
823 antibody (+) or a non-specific IgG antibody as a control (-). Inputs and IP samples were

824 immunoblotted for HA, Arp5 and H2A.Z. The western for Pcf11-HA was over-exposed in
825 order to detect the background levels of Pcf11 binding to the beads. All analysis was
826 conducted from the same SDS-page gel.

METHODS

Bioinformatics Tools and genome annotations

Unless otherwise indicated, version of the tools used for all bioinformatics analyses are as follows:

Samtools version 1.10

Bedtools version 2.29.2

Bowtie2 version 2.4.1

Hisat2 version 2.2.0

R version 3.6.2

BamCoverage version 3.5.0

Fastqc version 0.11.9

Cutadapt version 2.10

Trim_galore 0.6.4

MarkDuplicates version 2.23.1

FeatureCounts version 2.0.0

The *Saccharomyces cerevisiae* reference genome (S288C version R64-2-1) was downloaded from Saccharomyces Genome Database (<https://www.yeastgenome.org/>). The annotation used in the analysis for mRNA genes was produced by Antonin Morillon's lab, and based on CAGE-seq. This also includes the following annotations: XUT genes from ⁸³, SUT and CUT genes from XUT et al (2009) and NUT genes from ¹⁶. Annotations for other transcript types (snRNA, snoRNA, etc) were downloaded from Saccharomyces Genome Database.

The *Schizosaccharomyces pombe* reference genome and annotation (ASM294v2.47) were downloaded from pombase (www.pombase.org). Only protein coding genes were used in this analysis.

NET-seq analyses

NET-seq was performed from yeast strains containing Rpb1-FLAG (3XFLAG), alone or along with deletion of *INO80*. All strains appeared fully functional, with identical Ser2 and Ser5 phosphorylation levels on Rpb1 C-terminal domain and identical growth rates to the respective untagged strains (data not shown). NET-Seq libraries were constructed from biological duplicates of YM903 (*ino80Δ*, *RPB1-FLAG*) and YM885 (WT, *RPB1-FLAG*) cells and sequenced as previously described⁸⁴. Reads shorter than 10 nt were filtered out. Reads were mapped with Bowtie2 using default parameters. Duplicates reads were marked using Picard MarkDuplicates. Coverage files (bigWig) were produced by custom script. Reads locations from the alignment files (bam) were turned into bed files using bedtools bamtobed (with « -split » option), ignoring duplicates reads and reads with mapping quality below 30, piled up along the genome and turned into bigWig files using a python script. FeatureCounts was used for quantification with options « -O --fraction s 2 --ignoreDup ». Normalization factors were computed using DESeq2 method, using the whole count matrix. Travelling Ratio was computed as: (read density on gene body) / (read density on TSS), with gene body the region between TSS+200 nt to TTS and TSS the region from TSS to TSS + 200 nt. Read density was computed as : (# reads on region / region length) *1000.

4tU labeling and purification of newly synthesized RNAs

RNA labeling and purification were performed as previously described with some minor adjustments^{45,85}. Briefly, 20 mL of wildtype and mutant *S. cerevisiae* cells were grown at 30°C to an OD600 ≈0.8 in YPD. Newly synthesized (ns) RNAs were labelled for 6 min with 4-thiouracil (4tU, Sigma-Aldrich) added to the yeast cultures to a final concentration of 5 mM. Similarly, *S. pombe* RNAs were labeled for 6 min in YES medium at 32°C. Cells were pelleted directly after labeling and flash frozen in liquid nitrogen. All experiments were performed in biological triplicates. Prior to RNA extraction *S. cerevisiae* and *S. pombe* cells were mixed in a ratio of 3:1 and total RNA was extracted with Ribopure Yeast Kit (Ambion,

Life Technologies) according to the manufacturer's guidelines. 150 µg of total RNA were biotinylated for 3 hours at room temperature using 200 µL of 1 mg/mL EZ-link HPDP-Biotin (Pierce) with 100 µL of biotinylation buffer (100 mM Tris- HCl pH 7.5, 10 mM EDTA) and 100 µL of DMSO adjusted to a final volume of 1 mL with DEPC-treated RNase-free water (Sigma-Aldrich). After biotinylation, excess biotin was removed by mixing 1 mL of chloroform to the reaction and the liquid phases were separated by centrifugation for 5 min at 4°C and max speed. The aqueous phase was recovered and precipitated with isopropanol (1/10 volumes 5M NaCl and 2.5 volumes isopropanol). The recovered RNA was resuspended in 100 µL DEPC-treated RNase-free water and incubated for 10 min at 65°C followed by 5 min on ice. nsRNAs were bound to 100 µL of µMACS streptavidin microbeads (Miltenyi Biotec) for 90 min at room temperature and purification was performed using the µMACS streptavidin starting kit (Miltenyi Biotec). Columns were first equilibrated with 1 mL of washing buffer (100 mM Tris-HCl at pH 7.5, 10 mM EDTA, 1M NaCl, 0.1% Tween20). Samples were loaded and the flow-through was reapplied 2 times to the columns. The columns were washed five times with increasing volumes of washing buffer (600, 700, 800, 900, and 1000 µL). Ultimately, labeled RNAs were eluted twice with 200 µL of 100mM DTT. nsRNAs were precipitated overnight in 1/10 volume of 3 M NaOAc, 3 volumes of 100% ethanol and 20 µg of RNA-grade glycogen. The RNAs were recovered by centrifugation and RNA pellets were wash with ice-cold 70% ethanol and resuspended in 20 µL of DEPC-treated RNase-free water (Sigma-Aldrich). Samples were stored at -80°C until further use. Differential gene expression analysis was performed using DESeq2 1.16.1 Bioconductor R package on *Saccharomyces cerevisiae* counts normalized with size factors computed by the median-of-ratios method proposed by Anders and Huber on *Schizosaccharomyces pombe* counts (Anders and Huber 2010). cDTA analysis was performed as described (Schwalb et al. 2012).

917

918 **Total RNA-seq**

919 Yeast strains were processed in duplicate. ERCC RNA Spike-in control mixes (Ambion,
920 catalogue #4456740) were added to 1µg of total RNA according to manufacturer. Ribosomal
921 RNAs were depleted from total RNA using the RiboMinus™ Eukaryote v2 Kit (Life
922 Technologies). Depletion efficiency and quality control of rRNA-depleted RNA was assessed
923 by analysis in RNA Pico 6000 chip for 2100 Bioanalyzer (Agilent). Total RNA-seq libraries
924 were prepared from 50ng of rRNA-depleted RNA using the TruSeq® Stranded Total RNA
925 Sample Preparation Kit (Illumina). Paired-end sequencing (2x50 nt) was performed on a
926 HiSeq 2500 sequencer giving between 65 and 84 million reads. Reads were mapped using
927 version 2.0.6 of TopHat, with a tolerance of 3 mismatches and a maximum size for introns
928 2Kb. Tags densities were normalized on spike-in controls for all subsequent analyses.

929 **ChIP-exo**

930 The ChIP-exo assay has been previously described (Rhee HS, Pugh BF. ChIP-exo method for
931 identifying genomic location of DNA-binding proteins with near-single-nucleotide accuracy.
932 Curr Protoc Mol Biol. 2012;Chapter 21:Unit 21). In brief, yeast strains were grown to
933 exponential phase in yeast extract peptone (YP) + 2% dextrose (30°C to OD600 nm = 0.8),
934 then subjected to 1% formaldehyde crosslinking for 15 min at 25°C. After quenched with
935 125mM final concentration of glycine for 5 min, cells were harvested and washed. Sonicated
936 chromatin was prepared by standard methods. Standard ChIP methods were used for histone
937 H3 (antibody Ab1791, Abcam) followed by lambda exonuclease treatment and library
938 construction. Libraries were sequenced on an Illumina 2000 sequencer. Reads were uniquely
939 mapped to the reference genome (sacCer3 build) using version 2.1.0 of Bowtie2 with a
940 tolerance of 1 mismatch in seed alignment. Data were normalized on the total number of
941 uniquely mapped reads, for each sample.

Cell proliferation analysis in liquid media

Liquid growth rate analysis was conducted using the CG-12 robot (S&P Robotics Inc.). Yeast cells transformed with a URA3-containing plasmid (pRS416) and grown exponentially in SC-ura at 30°C were diluted to OD₆₂₀ 0.1 in either SC-ura or SC-ura + 50µg/ml 6-AU and four 150µl samples from each strain were plated onto 96-well transparent plates covered with breathable films. Plates were incubated at 30°C for several days and OD₆₂₀ was measured in the CG-12 robot (S&P Robotics Inc.) every hour with a shaking of 1000rpm for 1 minute before each read. Liquid growth rate analysis was not possible in the *nrd1-5* and associated strains due to flocculation. All cell proliferation experiments were repeated at least twice.

Growth rates analysis on agar plates

Growth of yeast strains was compared by plating 5-fold serial dilutions on SC / SC-inositol, SC-ura / SC-ura + 50µg/ml 6-azauracil (6-AU, Sigma), SC-leu / SC-leu + 0.4mM CuSO₄ (Sigma) or SC-leu / SC-leu + 0.25 CuSO₄ and incubating the plates at 30°C for several days. All plating experiments were performed at least three times.

RT-qPCR

Total RNA was extracted either with RNeasy Mini Kit (Qiagen) or by classical acid phenol-chloroform extraction. RNAs abundance was measured with SuperScript® III Platinum® SYBR® Green One-Step qRT-PCR Kit (Invitrogen) using specific primers for the targets of interest in a 10µl reaction volume, on Applied Biosystem Step-One Plus machines. RNAs abundance of each sample was compared with standard curves analysis. Abundance of *CUP1* from transcriptional read-through analyses using the *ACT-CUP* reporter system was compared to *ACT** RNA specifically transcribed from the same plasmid (Extended Data Fig.5a). Abundance of *NRD1* promoter-proximal RNA (*NRD1* 5') was compared to levels of *NRD1* promoter-distal RNA (*NRD1* 3').

Co-immunoprecipitation

Benzonase-treated yeast cell extracts were incubated with 20µl Anti-FLAG Affinity Gel (Sigma Aldrich) in 10mM Tris-Cl pH 7.5, 150mM NaCl, 0.05mM EDTA, 0.5% NP40, 1X Protease Inhibitor Cocktail (Roche) and 0.01mM PMSF for 3h. Beads were washed twice in 10mM Tris-Cl pH 7.5, 150mM NaCl, 0.05mM EDTA, 1X Protease Inhibitor Cocktail (Roche) and 0.01mM PMSF and resuspended in SDS sample buffer. Western blot analyses were performed using Monoclonal anti-FLAG M2 antibody (Sigma F3165), Anti-HA tag antibody (Abcam, ab9110) and Anti-Arp5 antibody (Abcam, 12099). Images were acquired using Syngene G:BOX. The experiment was reproduced three times. Immunoprecipitations for H2A.Z and HA-tag were performed similarly on benzonase-treated yeast cell extract using 36µl Protein-A sepharose beads coupled with 6µl of appropriate antibody (Anti-H2A.Z, Active Motif 39647; Anti-HA tag, Abcam ab9110). Control immunoprecipitations (mock) were performed with a non-specific antibody (Anti-Rabbit IgG, Promega). Western blot analyses were performed using the following antibodies: Anti-HA, Anti-Arp5, Anti-H2A.Z and Anti-Rpb1 y-80 (Santa Cruz Biotechnology, sc-25758). After the immunoprecipitation for H2A.Z shown in Figure S6G, beads were washed twice in 10mM Tris-Cl pH 7.5, 150mM NaCl, 0.05mM EDTA, 1X Protease Inhibitor Cocktail (Roche) and 0.01mM PMSF, then washed a third time in the same buffer containing 300mM NaCl and finally resuspended in SDS sample buffer. All experiments were reproduced three times.

Ino80 inducible degradation

The assay for inducible degradation of Ino80⁸² was performed as previously described^{35,86}. Briefly, a degron tag was fused to INO80 (Ino80-td) in cells carrying the UBR1 gene, that encodes for the N-recognin Ubr1, under the control of the GAL1 promoter, and cells were transformed with the *ACT-CUP* plasmid reporter system (Extended Data Fig. 5a). Cells were grown in SC-leu media containing raffinose as carbon source at 25°C until OD600~0.6-0.7, then shifted to SC-leu media containing galactose to induce *UBR1* expression. Subsequently,

complete Ino80-td protein degradation by the Ubr1 pathway was induced by 3 hours of heat shock at 37°C. Cells were then immediately harvested by centrifugation at 4°C, 3500rpm for 3 minutes, then washed twice with ice-cold water and snap-frozen in liquid nitrogen for RNA analysis. Yeast cells carrying the GAL1-driven UBR1 gene along with an unmodified INO80 genes were use as control. Furthermore, both (GAL1-UBR1) and (GAL1-UBR1 Ino80-td) cells were grown in SC-leu media containing glucose as a negative control for UBR1 expression (Extended Data Fig. 5d, grey bars). RNA analysis was conducted by RT-qPCR as described above.

ChIP-qPCR

Chromatin immunoprecipitation was performed as previously described in (Papamichos-Chronakis M, Watanabe S, Rando OJ, Peterson CL. Global regulation of H2A.Z localization by the INO80 chromatin-remodeling enzyme is essential for genome integrity. Cell. 2011;144(2):200-13.). Sonication was performed on a Bioruptor® Pico sonication device (Diagenode) with ten 30-sec pulses with a 30-sec break between pulses. Immunoprecipitation was carried out with Anti-HA tag antibody (Abcam ab9110) and Anti-Rpb1 y-80 antibody (Santa Cruz Biotechnology, sc-25758) in parallel. The recovered DNA was subjected to quantitative real-time PCR using Platinum® SYBR® Green qPCR SuperMix-UDG Kit (Invitrogen) with specific primers for the targets of interest in 10µl reaction volume, on Applied Biosystem Step-One Plus machines.

RNA-IP

RNA immunoprecipitation was performed as described in (Selth LA, Gilbert C, Svejstrup JQ. RNA immunoprecipitation to determine RNA-protein associations in vivo. Cold Spring Harb Protoc. 2009;2009(6):pdb prot5234.). Sonication was performed on a Bioruptor® Plus sonication device (Diagenode) with two 15-sec pulses at 50% amplitude with a 1-min break

1016 between pulses. Immunoprecipitation was carried out with Anti-HA tag antibody (Abcam
1017 ab9110). The recovered RNA was analysed by RT-qPCR as described above.

1018 **De novo analysis of public ChIP-exo and CRAC data**

1019 NAB3 and POLII CRAC data were taken from GEO dataset GSE70191 and processed as
1020 described in ⁵⁶. NAB2 and MTR CRAC data were taken from GEO dataset GSE46742 and
1021 processed as described in ⁴. ChIP-exo H3 data were downloaded from NCBI SRA dataset
1022 SRA059355 and processed as described in ⁸⁷.
