In Brief

Retrotransposon proliferation poses a threat to germline integrity. Laureau et al., demonstrate that yeast *Ty3/Gypsy* LTR-retrotransposons co-opt a host transcription factor during gametogenesis. In defense, developing gametes block retrotransposon translation. Mammalian genes derived from *Ty3/Gypsy* are regulated during meiosis via equivalent circuitry, suggesting that host-transposon conflicts could shape emerging gene function.

Highlights

- *Ty3/Gypsy* retrotransposons co-opt a transcription factor for its activation in meiosis
- Host amyloid-like translational repressors block the *Ty3/Gypsy* life cycle
- In mammalian gametogenesis, equivalent regulators govern *Ty3/Gypsy*-derived genes
- Host-transposon conflicts may shape the regulation of emerging genes

SUMMARY

Retrotransposon proliferation poses a threat to germline integrity. While retrotransposons must be activated in developing germ cells in order to survive and propagate, how they are selectively activated in the context of meiosis is unclear. We demonstrate that the transcriptional activation of *Ty3/Gypsy* retrotransposons and host defense are controlled by master meiotic regulators. We show that budding yeast *Ty3/Gypsy* co-opts binding sites of the essential meiotic transcription factor Ndt80 upstream of the integration site, thereby tightly linking its transcriptional activation to meiotic progression. We also elucidate how yeast cells thwart *Ty3/Gypsy* proliferation by blocking translation of the retrotransposon mRNA using amyloid-like assemblies of the RNA-binding protein Rim4. In mammals, several inactive *Ty3/Gypsy* elements are undergoing domestication. We show that mammals utilize equivalent master meiotic regulators (Stra8, Mybl1, Dazl) to regulate *Ty3/Gypsy*-derived genes in developing gametes. Our findings inform how genes that are evolving from retrotransposons can build upon existing regulatory networks during domestication.

INTRODUCTION

The relationship between organisms and transposable elements is complex and fluctuating. For the organism, transposable elements can act as a reservoir for novel genes and drive genomic plasticity, but they are also key drivers of genome instability. Insertions can rearrange regulatory networks and alter gene expression patterns (Chuong et al., 2017; Mita and Boeke, 2016; Rebollo et al., 2012). More dangerously, insertion of transposable elements can disrupt genetic information, give rise to heterologies, and potentially provide sites for ectopic recombination (Warren et al., 2015). For the element, if it is to survive and proliferate, it must do so with minimal detriment and possible benefit to the host (Cosby et al., 2019; Haig, 2016).

Retrotransposons are a class of transposable elements that propagate through an RNA intermediate via a copy-and-paste mechanism. This mechanism preserves the original element while generating DNA copies, which are free to invade other loci. Retrotransposon proliferation has seemingly no intrinsic limit and poses an acute burden to the host genome. This burden is reflected in the repetitive fraction of genomes, which is primarily composed of retrotransposon-derived sequences. In this study, we focus on understanding the biology underpinning pro-

liferation of a class of long terminal repeats retrotransposons (LTR-retrotransposons), *Ty3/Gypsy*, during meiosis.

LTR-retrotransposons are divided into four superfamilies, based on structure and phylogeny: *Ty1/Copia*, *Ty3/Gypsy* (both represented in all eukaryotic lineages), *Bel-Pao* (found in metazoans but not mammals), and endogenous retroviruses (ERVs), which are found only in vertebrates (Wicker et al., 2007). *Ty3/Gypsy* and ERVs are closely related because many vertebrate retroviruses likely arose from *Ty3/Gypsy* retrotransposons that acquired the envelope gene from other viruses (Hayward, 2017). Although no active *Ty3/Gypsy* retrotransposons are found in mammalian genomes, several sequences derived from *Ty3/Gypsy* are present, many of which have been domesticated for cellular functions (Volf, 2009).

The *Ty3/Gypsy* life cycle is much like that of a retrovirus except that it occurs entirely within the cell. It is transcribed into an mRNA that encodes 2 polypeptides: Gag3 and Gag3-Pol3 (Figure 1A). Gag3 is the precursor to the capsid (CA) and nucleocapsid (NC) proteins and Pol3 is the precursor to a protease (PR), a reverse transcriptase-RNaseH (RT-RH), and an integrase (IN). In most cases, only Gag3 polypeptide is translated, while Gag3-Pol3 is only produced by a frameshift that occurs in 5%–10% of translation events (Farabaugh et al., 1993) (Figure 1A).

Figure 1. *Ty3* Expression Is Coordinated with Meiotic Progression

(A) Diagram of the SK1 *Ty3* element DNA locus, full-length mRNA, and two polyproteins, Gag3 (precursor of CA-capsid SP-spacer and NC-nucleocapsid proteins) and Gag3-Pol3 (precursor of the aforementioned proteins and of PR-protease, RT-RH-reverse transcriptase—RNaseH and IN-integrase proteins). Colored lines indicate the positions of the Northern probes used in this study: *Ty3* probe (maroon), CA probe (orange), PR probe (yellow), RT probe (green), IN probe (blue). (B) $\log_2$ tag density of polyA-RNA-seq reads of *Ty3* locus from synchronized meiotic cells (Crick strand top). Cells harboring *NDT80-IN* (*NDT80* inducible strain B119) were sporulated at 30°C. Shown are the time points at 0, 3, 6, 7, 8, and 9 h post transfer to sporulation medium. At 6 h when cells had arrested in G2 due to the lack of Ndt80 meiotic transcription factor, they were released from the block by addition of 1 μ M β -estradiol (biological replicates = 2). (C and D) Full-length *Ty3* mRNA is expressed in meiosis. Sporulation was induced in wild type diploid strain (B47, purple) and in *ty3 Δ* diploid strain (B837, gold). (C) *Ty3* mRNA and *rRNA* (loading control) levels are shown (S, premeiotic DNA replication; G2, meiotic prophase; MI, first meiotic division; MII, second meiotic division). Full-length *Ty3* mRNA (5 kb) is indicated by a black arrow. Empty arrowheads indicate 18S and 25S *rRNA* (1.8 and 3.4 kb), which are both reported on the probed blot and serve as size markers. (D) Kinetics of meiotic progression was determined via DAPI nuclear staining. Shown are representative results of ≥ 5 biological replicates. (E–G) *Ty3* is activated during meiosis in wild *S. cerevisiae*. Wild type SK1 (B47, purple) and wild European strain OS673 (green, described in Peter et al., 2018) were induced to sporulate as in (C). (E) *Ty3* mRNA and *rRNA* levels are shown. (F) The number of *Ty* elements in SK1 and OS673 are shown. (G) Kinetics of meiotic progression determined by DAPI nuclear staining (biological replicates = 2).

Gag3 assembles with a *Ty3* mRNA dimer and Gag3-Pol3 into a remarkable structure within the cell—the virus-like particle (VLP)—inside which the precursor proproteins mature into their final products and the *Ty3* mRNA is reverse transcribed into cDNA (Garfinkel et al., 1985). This cDNA copy is bound to integrase proteins and can enter the nucleus via the nuclear pore to integrate in the genome. *Ty3* integration events require binding

to polymerase III, and thus, frequently occur in close proximity to tRNA genes (Qi et al., 2012).

For a retrotransposon to increase its copy numbers and proliferate through generations, it must do so in cells that will ultimately become gametes. For this reason, retrotransposons tend to be expressed in the developing germline, including during meiosis (Crichton et al., 2014; Ribeiro-dos-Santos et al.,

1997). However, as retrotransposon mobilization in these cells can cause heritable mutations and trans-generational genetic instability, organisms have evolved elegant multilayered mechanisms, which act at various stages of the retrotransposon cycle to protect their germlines (Crichton et al., 2014).

For example, transcription of retrotransposons can be repressed by DNA methylation, chromatin modifications, and transcriptional interference (for review (Crichton et al., 2014; Yang and Wang, 2016)). Post-transcriptional pathways, such as miRNA, siRNA, and piRNA, target retrotransposon mRNA for degradation (Bao and Yan, 2012; Dechaud et al., 2019; Yang and Wang, 2016) and RNA modification enzymes, such as cytidine deaminases, prevent reverse transcription of the retrotransposon mRNA into cDNA (Orecchini et al., 2018). Post-translational regulatory mechanisms act in germ cells to target retrotransposon proteins for premature degradation (MacLennan et al., 2017). Beyond the obvious long-term consequences of uncontrolled retrotransposon proliferation, dysregulation of retrotransposon control can cause acute failures in gamete development. Disruption of defense mechanisms in mice or *Drosophila* leads to sterility (Barau et al., 2016; Bourc'his and Bestor, 2004; Wang et al., 2018), and hyperactivation of retrotransposons causes fetal oocyte attrition in mice (Malki et al., 2014).

Here, we show that *Ty3/Gypsy* elements can exploit the genomic environment at their integration sites to ensure transcriptional activation during meiotic divisions. Our results illustrate a mechanism by which retrotransposons can restrict their expression to a developmental context in which activation is beneficial. We also identify an opposing mechanism by which cells defend their genome against meiotic retrotransposition. Developing budding yeast *Saccharomyces cerevisiae* gametes utilize amyloid-like RNA-binding protein assemblies to repress *Ty3* translation, thereby halting the proliferation cycle. We find that both the co-opting of meiotic regulators by *Ty3/Gypsy* elements and their interaction with assembly-forming RNA-binding proteins are strategies that are also employed by *Gypsy*-derived genes in mammals. Our findings highlight the likely hundreds of millions of years of perpetual interactions among retrotransposons, host RNA-binding proteins, and genomes.

RESULTS

Ty3 Is Expressed in Coordination with Meiotic Progression

We first determined whether retrotransposons are transcriptionally active during *S. cerevisiae* meiosis (strains used in this study are described in Table S1). We performed RNA-seq at hourly time points from cells undergoing synchronous meiosis using the *NDT80* block-release system (Benjamin et al., 2003; Carlile and Amon, 2008). There was only one full-length copy of *Ty3* in the SK1 strain, and we observed that this locus was transcribed in the sense orientation, specifically during the meiotic divisions (Figures 1A and 1B). We also observed an antisense RNA at the onset of meiosis that declined to almost undetectable levels as meiosis proceeded. These data led us to hypothesize that transcription of the full-length *Ty3* is repressed in mitotic cells but is activated during the meiotic divisions.

Only a full-length retrotransposon mRNA can complete the steps necessary for proliferation. While our RNA-seq data imply

that the *Ty3* locus is transcribed in meiosis, we sought to differentiate whether this was indicative of bona fide full-length transcripts or of cryptic inactive transcripts that span the locus. Using Northern blot analysis, we observed several *Ty3* RNA isoforms (Figure 1C), consistent in size with the various isoforms spanning the locus in the RNA-seq (Figure 1B), including a prominent band of the size of a full-length transcript (5 kb). All of the RNA isoforms we observed were specific to *Ty3* because none of them were produced in cells lacking *Ty3* (*ty3Δ*) (Figures 1C, S1A, and S1B). Using probe tiling, we were able to identify this top band as a full-length mRNA, containing both *GAG3* and *POL3* coding sequences (Figure S1C) and thus the potential capacity to propagate. Strikingly, full-length *Ty3* mRNA was expressed and reached maximal levels at the first meiotic division (Figures 1C and 1D).

We next determined whether meiotic transcriptional activation of *Ty3* occurs in other *S. cerevisiae* isolates. Because rapid, efficient, and synchronous meiosis is a feature that is not shared by most lab strains, we decided to investigate a collection of wild diploid isolates (Peter et al., 2018) for sporulation efficiency and *Ty3* activation (Table S2). These strains harbor varying *Ty3* copy numbers. We found that full-length *Ty3* transcription switches on at the time of meiotic divisions in at least one isolate, OS673, which harbors two full-length copies of *Ty3* (Figures 1E–1G; Table S2). This strain was isolated from a beetle in Hungary (Peter et al., 2018) and is of a completely different genetic background than SK1 (~51,400 SNPs), allowing us to rule out the possibility that *Ty3* activation in meiosis is a peculiarity that appeared during lab domestication. From these data, we conclude that *Ty3* retrotransposons have evolved to activate, and potentially proliferate, during meiosis.

Ty3 Expression Is Controlled by a Critical Meiotic Transcription Factor

How is *Ty3* transcription activated specifically at the onset of meiosis I? The transition from meiotic prophase to the first meiotic division is governed by the meiosis-specific transcription factor Ndt80 (Xu et al., 1995). Accordingly, we asked whether *Ty3* is under the control of Ndt80. If *Ty3* is a Ndt80 target, it would not be transcribed in meiotic cells deprived of Ndt80. Furthermore, *Ty3* transcription should be selectively activated upon ectopic Ndt80 activity. We found that cells in which *NDT80* is not induced—and are thus arrested in meiotic prophase—do not express *Ty3* mRNA (Figures S2A and S2B). Additionally, in meiotic cells where *NDT80* expression is delayed, *Ty3* transcription exhibits a corresponding delay. We observed that *Ty3* full-length transcripts accumulate from 15 to 30 min before metaphase I and persist until exit from anaphase II (Figures 2A and 2B). These results imply that *Ty3* is a target of Ndt80.

In further support of this idea, *Ty3* is integrated downstream of two Ndt80 binding sites (79 bp and 269 bp) (Figure 2C). To investigate whether *Ty3* meiotic transcription activation is governed by its environment of integration rather than elements within its 5' LTR, we asked if *Ty3* is still transcribed in cells harboring a promoter-gene cassette (*HIS3MX*) between the 5' LTR and the first proximal Ndt80 binding site (Figure S3A). We found that *Ty3* was no longer transcribed when we separated it from its upstream genetic context (Figure S3B). To test whether Ndt80 directly activates *Ty3*, we mutated the two Ndt80 binding sites upstream of

Figure 2. Ty3 Exploits Binding Sites of a Meiotic Transcription Factor from the Integration Environment

(A and B) Ty3 expression is controlled by Ndt80

(A) Sporulation was induced in parallel in wild type (B47, purple), and in *NDT80-IN* (B48, blue, released from the G2 block at 6 h). Ty3 mRNA and rRNA levels are shown. Asterisk indicates a degraded RNA sample, which is excluded from the quantification shown in (B).

(B) Solid lines indicate quantification of RNA levels from (A), dashed lines indicate kinetics of meiotic divisions analyzed by tubulin immunofluorescence (quantification of cells containing meiotic spindles). Shown are representative results of ≥ 5 biological replicates.

(C and D) Ty3 transcription is directly activated from Ndt80 binding sites upstream of the integration site. Diagram of endogenous and mutated Ty3 upstream context. (C) Blue triangles indicate Ndt80 binding sites (CACAAA) and yellow triangles indicated mutated binding sites (AAAAAA) (–79 and –269 bp upstream of Ty3).

(D) Sporulation was induced in *NDT80-IN* strains containing the wild-type Ty3 Ndt80 binding sites (B1864, blue), or with mutated Ndt80 binding sites (B1885, yellow) as in (A) (in both strains, a *kanMX* marker was inserted 353 bp upstream the Ty3 5' LTR). Ty3 mRNA and rRNA levels are shown. Shown are representative results of 2 biological replicates.

(legend continued on next page)

Ty3 (CACAAA to AAAAAA) and assessed the effect of these mutations on meiotic Ty3 transcription (Figure 2C). We found that point mutation of these sequences specifically abolished full-length meiotic Ty3 transcription (Figure 2D). To assess whether Ndt80 binds upstream of Ty3 during meiotic progression, we conducted a meiotic time course analysis of Ndt80 binding by ChIP-seq. We analyzed Ndt80 binding at 0, 3, 5, and 6 h in meiosis. We chose these time points because Ndt80 levels are highest at ~5–6 h in meiosis (Figure 2E). In support of the hypothesis that Ty3 is transcriptionally activated by Ndt80, we found that Ndt80 binds upstream of Ty3 as meiosis progresses (Figure 2F). We conclude that Ty3 co-opts a host regulatory circuit to coordinate its activation with meiotic division and we predict that other retroelements could have evolved a similar strategy to acquire germline-specific activation.

The Ndt80 protein sequence as well as its binding site is conserved among yeasts from *Saccharomyces* to *Candida* (Nocedal et al., 2017). We thus sought to determine whether Ty3 control by Ndt80 is conserved among other *Saccharomyces*. We assessed the presence of Ndt80 binding sites within and upstream of full-length Ty3 elements in seven *S. cerevisiae* and five *S. paradoxus* genomes for which all Ty elements have been mapped and annotated (Yue et al., 2017) (spanning approximately 5 million years of evolution (Shen et al., 2018)) (Figure 3A). Among twenty full-length Ty3 elements, we found that thirteen harbor one or more Ndt80 binding sites within 1 kb upstream of their integration sites, including five cases where the Ndt80 binding site is less than 250 bp upstream the integration site (Figure 3A). Within the 1-kb regions upstream of Ty3 elements, we observed that several of them harbor multiple Ndt80 binding sites. In total, we observed nineteen Ndt80 binding sites within the 20-total kb, which is significantly higher than what would be expected by chance (Z score 2.7; $p < 0.01$).

Because Ndt80 binding sites are abundant (about 8,000 per genome), we needed to ascertain whether the distance of a Ndt80 binding site from a locus is predictive of whether that locus is truly activated by Ndt80. Ndt80-responsive genes are well defined in SK1 meiosis (Chu et al., 1998). We first compared the enrichment of Ndt80 binding sites upstream of Ndt80 target genes and non-target genes and found a peak of enrichment within the 50 to 250-bp region upstream of the transcription start sites (TSS) in target genes (Figure 3B). We next asked whether the association between Ty3 elements and Ndt80 binding site resembles that of Ndt80 targets or non-targets. Because the small number of full-length Ty3 found in the *Saccharomyces* mentioned above gave us limited statistical power, we combined full-length elements with Ty3 solo-LTRs ($n = 498$), which are the vestiges of Ty3 integrations lost by homologous recombination between LTRs. We found that taken together, Ty3 elements showed a significant enrichment of Ndt80 binding sites 200 bp upstream of their integration site compared to non-targets ($p < 0.001$, Figure 3B). This result strongly supports the hypothesis

that the co-opting of Ndt80 by Ty3 elements is a recurring feature.

Ty3 Translation Is Repressed Specifically in Meiosis

Ty3 has co-opted a meiotic control element to activate its transcription specifically during meiosis. We next sought to determine how yeast responds to protect its developing gametes from the potential threat of Ty3 proliferation. Because the Ty3 copy number seems to be relatively low and stable in yeast strains (Table S2), we reasoned that yeast cells might have evolved a defense mechanism that acts post-transcriptionally. We first wanted to ascertain whether Gag3 protein is produced in meiosis. We found that Gag3 was produced in our positive control—exposure of MATa SK1 haploid cells to α -factor mating pheromone (Figure 4A)—a condition in which full-length Ty3 RNA was shown to be both transcribed and translated in another lab strain via the transcription factor Ste12 (Bilanchone et al., 1993). Hence, we confirmed that Ty3 is an active element in SK1. However, despite the presence of full-length Ty3 mRNA in meiosis, no detectable Gag3 protein was produced (Figure 4A). The absence of Gag3 protein in meiosis could be due to the lack of translation or rapid protein degradation. To test the latter possibility, we inhibited proteasomal function in meiotic cells. We found that either genetic (*rpn6-1* (Isono et al., 2005)) or chemical inhibition (MG-132) of the proteasome did not result in Gag3 protein accumulation (Figure S4A). We concluded that the absence of Gag3 in meiosis is not due to degradation by the proteasome. Instead, our data support a model by which, in response to Ty3 transcription in meiosis, yeast cells respond by preventing translation of the mRNA thereby halting the retrotransposition cycle.

Because Ty3 mRNA can be translated upon exposure of MATa cells to α -factor pheromone, we suspected that translational repression of Ty3 is specific to meiosis. To test this hypothesis, we ectopically expressed *NDT80* in haploid mitotic cells to drive Ty3 transcription. In parallel, we depleted the mitotic repressor Sum1 that binds upstream of Ndt80 target genes to inhibit their inappropriate expression (Klutstein et al., 2010; Pierce et al., 2003; Winter, 2012). Selective depletion of Sum1 was achieved using the auxin-inducible degron system (Morawska and Ulrich, 2013). We found that when we expressed *NDT80* in mitotic cells either in the presence or absence of Sum1 (Figure S4B), Ty3 was both transcribed and translated (Figure 4B). Ty3 mRNA and protein levels were much higher when Sum1 was depleted. We also observed that upon *NDT80* activation in meiosis or mitosis, Ty3 mRNA levels were similar, while translation occurred only in the mitotic context. In addition, we observed that Ty3 mRNA dimers, which are indicative of VLP assembly (Cristofari et al., 1999; Feng et al., 2000), form upon *NDT80* induction in mitosis but not in meiosis (Figure S4C). We conclude that the mechanism by which yeast represses translation of Ty3 mRNA is meiosis specific. These data also provide additional support to the notion that this retrotransposon has co-opted the Sum1/Ndt80 regulon to restrict its expression to meiosis.

(E and F) Ndt80 binds directly upstream of Ty3 integration sites as meiosis progresses. Sporulation was induced in wild-type diploid strain (B47 no tag) and in *NDT80-3V5* diploid strain (B1674). Shown are the time points 0, 3, 5, 6 h post-transfer to sporulation medium.

(E) Analysis of Ndt80 protein expression. Ndt80 (tagged with 3V5) and Pgk1 (loading control) protein levels are shown. Migration of molecular size standards is indicated on right as kDa values.

(F) Browser tracks showing Ndt80-3V5 ChIP-seq peaks (blue bars). Ty3 (left) and *NDT80* (right, positive control) loci are shown.

Figure 3. Integration of Ty3 Downstream of Ndt80 Is a Recurring Phenomenon

(A) Left: phylogenetic relationships among seven *S. cerevisiae* (*S. c.*) strains and five *S. paradoxus* (*S. p.*) strains (Modified from Yue et al., 2017), along with their respective number of full-length Ty3 elements (total 20). Right: 2-kb window map of 1,000 bp upstream of full-length Ty3 elements with Ndt80 binding sites (CACAAA) indicated as blue triangles. Ndt80 binding sites are significantly enriched in this region (determined by Z test statistic of 100 randomized simulations; Z score 2.7; $p < 0.01$).

(B) Left: 260 SK1 genes were identified as Ndt80 target genes (Chu et al., 1998), and 5,291 as non-target genes. Within the 13 *S. c.* and *S. p.* strains analyzed above there are 518 Ty3 elements (20 full-length and 498 solo LTRs). Right: Comparison of the distribution of Ndt80 binding sites in the region 500 bp upstream of the TSS among target genes (teal), non-target genes (gray), and Ty3 elements (blue). Statistical significance was determined by bootstrap analysis ($p < 0.001$ at the -200 position).

Meiotic Ty3 Repression Is Mediated by the Translational Repressor Rim4

We next sought to elucidate the mechanism of Ty3 translational repression. Translational control of mRNA plays a central role in regulating gene expression during gametogenesis in virtually all sexual organisms (reviewed in Kronja and Orr-Weaver, 2011). In most organisms, transcription is shut off or limited during meiosis and regulation of gene expression relies on RNA-binding proteins that govern translation of previously transcribed mRNA. In *S. cerevisiae*, the RNA-binding protein Rim4 binds to and inhibits translation of mRNAs that encode protein products that are toxic when prematurely expressed but are necessary for late meiotic events (Berchowitz et al., 2013). We thus wanted to test whether repression of Ty3 translation was mediated by Rim4. Because Rim4 is required for meiotic entry, we designed a selectively degradable Rim4 using the auxin-inducible degron system (Morawska and Ulrich, 2013) such that we could deplete it just before activation of *NDT80*. We found that Ty3 was translated upon premature Rim4 depletion (Figure 5). Rim4 must be assembled into an amyloid-like state in order to repress translation of its targets, which requires the intrinsically disordered region (IDR) in its C terminus (Berchowitz et al., 2015). We found that *rim4ΔIDR* mutants also translate Ty3 (Figure S5). While our

genetic analyses do not allow us to distinguish whether Rim4 directly or indirectly regulates Ty3 translation, we conclude that Rim4 amyloid-like repressors function in part to protect the germline from the proliferation of retrotransposons.

Mammalian Gypsy-Derived Genes Are Regulated by Meiotic Transcription Factors

We next asked whether mammalian Ty3/Gypsy-like elements also exploit meiosis-specific transcription factors to activate during gametogenesis. In mammals, most Ty3/Gypsy LTR-retrotransposon/retrovirus-derived elements no longer retain their retrotransposition capacity and are classified based on whether Gypsy-internal sequences are present (28 loci in mouse and 693 loci in human contain these sequences) (Campillos et al., 2006; Kojima, 2018). To test if any mammalian Gypsy-derived genes are switched on during meiosis, we analyzed RNA-seq data from adult mouse testes (Soumilion et al., 2013). We found that several Gypsy-derived elements, including those that contain Gag-like internal sequence (MamGyp-int), are transcribed in testes during the meiotic stage of spermatogenesis (spermatocytes) and in postmeiotic round spermatids (Figure S6A). When we analyzed uniquely mapping RNA-seq reads of specific MamGyp-int loci, we found that two genes—*Moap1* and *Pnma1*—are

Figure 4. Ty3 Is Post-Transcriptionally Repressed in Meiosis

(A) Gag3 protein encoded by *Ty3* is not detectable during meiosis. Sporulation was induced in *NDT80-IN* (B48) as in 2A. *MATa* wild-type (B1) and *ty3Δ* (B827) haploid strains were exposed to α -factor (0, 0.5, 10 μ M) to induce *Ty3* activation. Left: *Ty3* mRNA (black arrow) and *rRNA* (white arrows) levels, and Gag3 (and its processed forms CA-SP, CA) and Pgk1 (loading control) protein levels are shown. Migration of molecular size standards is indicated on right as kDa values. Right: Quantification of *Ty3* full-length RNA (maroon) and Gag3 protein (green) normalized over their respective loading controls. Shown are representative results of ≥ 5 biological replicates.

(B) Post-transcriptional repression of Gag3 is specific to meiosis. To express *Ty3* in both meiosis and mitosis, we expressed *NDT80* in sporulating diploid cells (wild-type B48, *ty3Δ* B839) and in haploid mitotically dividing cells with and without the Sum1 transcriptional repressor (wild-type B477, Sum1-deg B829, and *ty3Δ* B827). *Ty3* mRNA (black arrow) and *rRNA* (white arrows) levels and Gag3 and Pgk1 (loading control) protein levels and quantification are shown, as in (A). Asterisks show unspecific bands (e.g., band in α -VLP present in *ty3Δ*; see also Figure S3B). Shown are representative results of 5 biological replicates.

supials that did not experience this expansion of *Pnma* genes and harbor only a single *Pnma* gene: *M-PNMA* (Kokošar and Kordiš, 2013). We analyzed tissue-specific RNA-seq data from opossum (Lesch et al., 2016; Marin et al., 2017) and found that *M-PNMA* mRNA is highly and specifically up-regulated in testes, particularly in pachytene spermatocytes (Figure S6B). These data suggest that meiotic transcription of *Pnma* was either present in the common therian ancestor or has convergently evolved independently in both eutherians and marsupials.

We next wished to investigate if the transcriptional activation of Gypsy-derived elements in meiosis reflects the capture of element-external meiosis-specific transcription factor binding sites. Motivated by our findings in yeast, we focused our investigation on two master transcriptional

highly upregulated in mouse meiotic spermatocytes (Figure 6A). Both *Moap1* and *Pnma1* are characterized as domesticated in mammals, and their open reading frames encode Gypsy-derived Gag-like proteins. Based on these analyses, we propose that, analogous to *Ty3* regulation in yeast, the Gypsy-like sequences *Moap1* and *Pnma1* are being transcriptionally activated in male mouse meiosis. In eutherian mammals, there has been a massive expansion of the *Pnma* gene family (15 genes in humans, 12 in mice; Campillos et al., 2006). We wanted to test whether meiotic transcription of *Pnma* can be observed in mar-

regulators of meiosis—Stra8 and Myb1 (also known as A-myb). Stra8 is required for meiotic initiation in mammals and promotes transcription of early meiotic genes (Anderson et al., 2008), whereas Myb1 becomes active early in meiosis and is required for meiosis to progress through pachytene (Bolcun-Filas et al., 2011). We assessed whether the meiotic transcription factors Stra8 and Myb1 bind upstream of *Moap1* and/or *Pnma1* using ChIP-seq data from adult mouse testes (Kojima et al., 2019; Zhou et al., 2017). We found that both Myb1 and Stra8 ChIP-seq peaks are present upstream of multiple *Moap1* TSSs

Figure 5. Ty3 Is Translationally Repressed by the RNA-Binding Protein Rim4

Meiosis was induced in three *NDT80-IN* diploid strains: wild-type (B48), Rim4-deg (B1022, Rim4-deg fusion strain, induced by auxin addition to 1 mM at $t = 5$ h), and *ty3Δ* (B389). Meiotic cells were released from the G2 block by addition of 1 μ M β -estradiol at 6 h. Mitotic samples were collected from the experiment shown in 3B and Figure S3B. Ty3 mRNA (black arrow) and rRNA (white arrows) levels and Gag3, Rim4 (Rim4-deg is tagged with FLAG, wild-type Rim4 is tagged with 3V5 in the first strain, and not tagged in the remaining strains), and Pgk1 (loading control) protein levels. Migration of molecular size standards is indicated on right as kDa values. Quantification of Ty3 mRNA and Gag3 protein relative to their respective loading controls are shown. Asterisks show unspecific bands (e.g., band in α -VLP present in *ty3Δ*; see also Figure S3B). Shown are representative results of 4 biological replicates.

(Figures 6B, S6C, and S6D). Similarly, a Mybl1 ChIP-seq peak overlaps the *Pnma1* TSS external to the MamGyp-int sequence (Figures 6B, S6C, and S6D).

If *Moap1* and *Pnma1* are under the direct control of *Stra8* and Mybl1, developing gametes that do not express these transcription factors should not produce these transcripts. To test this prediction, we analyzed whether *Moap1* and *Pnma1* are expressed in preleptotene *Stra8*^{+/−} and preleptotene *Stra8*^{−/−} spermatocytes (Kojima et al., 2019) or in P14 *Mybl1*^{+/−} and *Mybl1*^{−/−} testes (Zhou et al., 2017). In concordance with the ChIP-seq analysis, *Moap1* transcript abundance was significantly reduced in the absence of *Stra8* (Figure 6D). In addition, both *Pnma1* and *Moap1* transcript abundance was reduced in the absence of *Mybl1* (Figure 6E). Taken together, our data support the hypothesis that Gypsy elements co-opt critical meiotic transcription factors to ensure their expression in gametogenesis and that this regulation exists from yeast to mammals.

Mammalian Meiotic Translational Repressor Proteins Bind to GAG-Containing mRNA

In mammals, the functional orthologs of Rim4 are the DAZ family of RNA-binding proteins (Berchowitz et al., 2015). DAZ family proteins act as regulators of translation and exhibit a similar organization to Rim4 in that they harbor N-terminal RRM and a C-terminal prion-like domain (King et al., 2012). Furthermore, Dazl (DAZ-like) forms SDS-resistant amyloid-like assemblies specifically in mouse testes (Berchowitz et al., 2015). Thus, we asked if meiotic Gypsy-derived RNAs might be regulated by DAZ family proteins. We analyzed Dazl CLIP data generated from adult mouse testes (Zagore et al., 2018) and observed clear enrichment peaks within the 3' UTRs of *Moap1* and *Pnma1* transcripts (Figures 6B and 6C). In addition, we analyzed DAZL-RNA

complexes isolated by RIP in oocyte-containing human fetal ovaries (Rosario et al., 2017). We found that among human Gypsy-derived elements, the cognate human *MOAP1* and *PNMA1* transcripts are significantly enriched in DAZL immunoprecipitations (Figures 6F and S6E). Of all the 802 different types of retrotransposon expressed in this tissue, only five were enriched in the DAZL-RNA immunoprecipitations (Figures S6F and S6G). We propose that the physical interaction between DAZ family proteins and transcripts containing Gypsy-derived sequences exists in both mice and humans and in both male and female gametogenesis. Taken together, these data support an ancient association between amyloid-like RNA-binding assemblies and retrotransposon and retrotransposon-derived mRNA. We propose that this association possibly represents a functional repurposing of the retrotransposon defense mechanism we observed in yeast.

DISCUSSION

In this study, we elucidate mechanisms underlying an evolutionary battlefront, where retrotransposons attempt to proliferate in the germline and host organisms respond to defend the genomes of their progeny. Ty3/Gypsy retrotransposons in yeast and domesticated Gypsy-derived genes in mammals co-opt host master meiotic regulators to transcriptionally activate during gametogenesis. Based on these findings, we propose that the integration site of a retrotransposon can encode the critical regulatory information that the element requires to activate specifically during gamete development. We further show that yeast cells utilize a meiosis-specific translational repressor to thwart further progress in the retrotransposon life cycle. Likewise, transcripts from domesticated Ty3/Gypsy elements in mammals are bound by a cognate translational regulator. In the yeast strain SK1, we find that meiotic cells efficiently repress translation of Ty3 mRNA, which very likely prevents the element from proliferating in this context. However, because the control of retrotransposons by meiotic transcription

Figure 6. Mammalian Gypsy-Derived Genes Are Activated by Meiotic Transcription Factors and Regulated by Meiotic RNA-Binding Proteins

(A) Analysis of uniquely mapping MamGyp-int RNA-seq reads for MamGyp-int loci expressed during spermatogenesis in adult mouse testes. biological replicates = 3 for each stage.

(B and C) Browser tracks showing mouse testis Stra8-FLAG ChIP-seq peaks (orange bars, MACS2 $q < 0.05$), mouse testis Stra8-FLAG ChIP reads (orange line plot, fold change in ChIP relative to input, data from wild-type animals subtracted as background), mouse testis Mybl1 ChIP-seq peaks (blue bars, MACS2 $q < 0.05$), mouse testis Mybl1 ChIP reads (blue line plot, fold change relative to input), mouse testis Dazl CLIP clusters (green bars, biologically reproducible CLIP clusters), mouse testis Dazl CLIP (green line plot, number of CLIP tags), mouse spermatocyte RNA-seq (black histogram, counts per million mapped reads), Gencode VM18 gene models encompassing (B) *Moap1*, or (C) *Pnma1* (navy rectangles), and the genomic location of Gypsy-derived sequences (maroon rectangles).

(D) Expression of *Moap1* and *Pnma1* in *Stra8*^{-/-} preleptotene mouse spermatocyte RNA-seq data. CPM (counts per million) mapped reads (biological replicates = 2 for *Stra8*^{+/-} spermatocytes and = 3 for *Stra8*^{-/-} spermatocytes).

(E) Expression of *Moap1* and *Pnma1* in P14 *Mybl1*^{-/-} mouse testis RNA-seq data (biological replicates = 3).

(F) Analysis of MamGyp-int containing transcripts from *MOAP1* and *PNMA1* in anti-DAZL RIP from human fetal ovaries (biological replicates = 3).

Asterisks indicate $p < 0.05$ as determined by Student's t test.

factors occurs frequently in yeast, we expect this activation strategy to be successful in other strains and other organisms. Future studies will be necessary to determine the extent to which meiotic activation and host translational repression of *Ty3/Gypsy* elements can be generalized across organisms.

Arkhipova and Meselson put forth the idea that one of the major forces driving the pervasive maintenance of meiosis and sex is to allow organisms to focus defense strategies against transposable elements to a subset of cells (i.e., the germline) that will provide the genetic material for generations to come (Arkhipova and Meselson, 2005). In multicellular organisms, it is of obvious benefit to the retrotransposon to direct activation to the germline with the aim to elude host defense mechanisms. Why does the *Ty3* retrotransposon activate only during the sexual cycle (i.e., meiosis and mating) in a unicellular organism such as yeast? In unicellular organisms, the entire organism is the germline, and thus, coordination of retrotransposon activation with meiosis may seem less obvious. Retrotransposon activation poses a resource cost on the cell (reviewed in Bourque et al., 2018). In rapidly proliferating cells, this cost could indeed translate into a fitness disadvantage. When activation is restricted to meiosis and mating in yeast, *Ty3* remains latent, thus minimizing its fitness cost and focusing its efforts to proliferate in cells that are not cycling. Furthermore, linking retrotransposon proliferation to meiotic recombination (i.e., mixis) could be valuable for the element. Organisms can generate favorable allelic combinations via meiotic recombination. Retrotransposons could propagate into advantageous allelic combinations by activating during and post-recombination, which could offset the fitness cost of an additional element. Lastly, the programmed double-strand breaks that initiate meiotic recombination could provide access points for retrotransposon cDNA.

The transcriptional activation of LTR-retrotransposons is often governed by regulatory sequences within the LTRs themselves. For example, the 5' LTR of *Ty1/Copia* contains binding sites for several transcriptional activators, including Gcn4, Gcr1, Ste12, Tec1, and Tea1, as well as the repressor Mot3 (Servant et al., 2008). Likewise, the ability of *Ty3/Gypsy* to activate during mating (or upon α -factor exposure) relies on Ste12 binding within its 5' LTR (Bilanchone et al., 1993). However, in the situation described here, *Ty3* utilizes regulatory sequences upstream of its integration site. What selective pressures would then drive *Gypsy*-like elements to utilize external regulatory sites to activate during meiosis? We propose that there may be some advantages to decouple meiotic activation from the intrinsic properties of the element. Meiosis-specific genes are repressed during vegetative-somatic growth. As we mentioned above, in yeast, the Ndt80 binding site is also recognized by the repressor Sum1 (Klutstein et al., 2010; Pierce et al., 2003). If this sequence was harbored in the 5' LTR, the element could be condemned to a single strategy by virtue of the presence of Sum1 in non-meiotic contexts. By utilizing external regulatory elements, the element can avoid intrinsic repressor binding sites while gaining the flexibility to utilize other transcription activators that may be advantageous in other selective contexts.

As illustrated in decades of previous work, the study of *Ty* elements is a powerful model for the discovery and elucidation of host mechanisms that restrict retrotransposition (Maxwell and Curcio, 2007). Genetic screens designed to identify factors that

influence *Ty1* (Griffith et al., 2003; Scholes et al., 2001) and *Ty3* (Aye et al., 2004; Irwin et al., 2005) retrotransposition have shown that RNA processing factors can positively and negatively influence *Ty* retrotransposition. Three RNA processing factors suppress both *Ty1* and *Ty3* retrotransposition: the DEXH-box RNA helicase Dbp3, the ribosomal protein Rpl6A, and the lariat-debranching enzyme Dbr1. Studies motivated, in part, from these screens have identified that mRNA-processing bodies (P-bodies) (Beliakova-Bethell et al., 2006) and nucleoporins (Rowley et al., 2018) play important roles in the life cycle of *Ty3* elements. Here, we show that host repression of *Ty3* is either directly or indirectly carried out by amyloid-like assemblies of the RNA-binding protein Rim4. In future studies, it will be exciting to assess whether and how Rim4 assemblies interact with these factors to defend the host genome against retrotransposon proliferation.

Rim4 binds to and represses the translation of numerous mRNAs that encode proteins required for late meiotic events. While many of these targets are translated precisely at meiosis II onset, several others are translated later (Berchowitz et al., 2013; Brar et al., 2012) and apparently some, such as *Ty3*, are seemingly never translated. We hypothesize that the fate of Rim4 targets is dictated by interaction with other factors. This hypothesis is consistent with the developmentally regulated clearance of Rim4 multimeric assemblies at meiosis II onset (Carpenter et al., 2018). Targets that are translated significantly after meiosis II onset likely interact with the RNA-binding proteins Pes4 and Mip6 (Jin et al., 2017), and we speculate that the terminal repression we observe for *Ty3* is carried out by a factor unknown to us.

To escape Rim4-mediated translational repression, *Ty3* could take advantage of a particular feature of the meiotic stage at which it is expressed. Prior to meiotic prophase exit, cells can return to a mitotic cycle if nutrients are sensed by the cell in a process known as "return to growth," which is a common event in the life cycle of wild yeast (Brion et al., 2017; Tsuchiya et al., 2014). *Ty3* mRNA accumulates 15–30 min before the meiotic commitment point. Upon return to growth, Rim4-mediated translational control is relieved (Jin et al., 2017), and, therefore, *Ty3* would recover the ability to propagate in a post-mixis environment. Similarly, if *Ty3* mRNA persists until the end of gametogenesis and into spores, germination would likely provide a permissive environment for *Ty3* propagation. This strategy would be analogous to what is observed in LINE-1 elements, which are expressed during mouse gametogenesis and then only reintegrate after fertilization during early embryonic development (Kano et al., 2009).

While the proliferation of *Ty3/Gypsy* elements is often deleterious, it is possible that their evolutionary cost is offset by providing an activity or function that is beneficial to the host (Cosby et al., 2019). Our preliminary results suggest that *Ty3* deletion mutants do not exhibit a detectable defect (or advantage) in any aspect of gametogenesis, including meiosis, spore formation, and/or spore viability. However, we speculate that mutations in other *Ty* elements could be different in this regard. One exciting speculation is that, by integrating downstream of meiosis-specific regulatory elements, a new coding sequence is now readily available to be domesticated for a meiosis-specific function. Similarly, the interaction of retrotransposons with

regulatory RNA-binding proteins could connect the evolving gene to additional regulatory pathways. Retrotransposons are ripe for domestication because they encode several proteins with diverse and useful domains (Volf, 2006). Possible examples of meiotic genes evolving from *Gypsy* sequences include the mammalian *Gypsy*-like elements *Moap1* and *Pnma1*, which do not represent active retrotransposons and are likely domesticated. We observe meiotic transcriptional activation of *Pnma* genes in mouse, human, and opossum, and while meiosis-specific activation of *Gypsy*-like elements is unlikely to be generalizable among all copies of these elements within a species, it appears to be generalizable to some degree among species. Remarkably, the single *Pnma* gene (*M-PNMA*) in opossum is highly upregulated in pachytene spermatocytes. Whether this represents the ancestral expression pattern of *Pnma* or convergent evolution, we speculate that meiotic activation of *Pnma* is providing some benefit to the organism and is being selected for. Because *Pnma* is inactive for retrotransposition, we propose that during the time when *Gypsy* elements were still retrotranspositionally active and co-opting meiotic transcription factors for their own benefit, they acquired beneficial functions in the host meiotic cells. It is exciting to us that the regulatory circuitry established during the evolutionary battle between host and retrotransposon could also give direction as to how and when the emerging gene will function. It will be important to investigate the emerging roles of these elements and how they are repurposing retrotransposon regulatory mechanisms in the process of acquiring functions and evolving into new genes.

We propose that the co-opting of meiosis-specific transcription factors by retrotransposons represents an ancient strategy to coordinate retrotransposition with germline development. Correspondingly, translational repression of retrotransposons by host RNA-binding proteins could also be an ancient and preserved feature of meiosis. We can add this mechanism to the elaborate repertoire of retrotransposon defense systems such as piRNA, DNA methylation, and heterochromatic DNA condensation. It will be interesting to assess whether other assembly-forming RNA-binding proteins intervene in the life cycles of other retrotransposons in other organisms.

STAR★METHODS

Detailed methods are provided in the online version of this paper and include the following:

- **KEY RESOURCES TABLE**
- **RESOURCE AVAILABILITY**
  - Lead Contact
  - Materials Availability
  - Data and Code Availability
- **EXPERIMENTAL MODEL AND SUBJECT DETAILS**
  - Yeast Strains and Constructs
- **METHOD DETAILS**
  - Yeast Growth and Sporulation Conditions
  - Meiotic Progression Analysis
  - Northern Blot Analysis
  - Yeast RNA Sequencing and Sequencing Analysis
  - Immunoblot Analysis
  - Ndt80 ChIP-seq

● QUANTIFICATION AND STATISTICAL ANALYSIS

- Statistical Analysis for Ndt80 Binding Site Enrichment Upstream Ty3 Insertions
- Analysis of Yeast ChIPseq Data
- Analysis of Mammalian RNAseq Data (Mouse, Opossum)
- Analysis of Mammalian ChIPseq Data (Mouse)
- Analysis of Dazl CLIP and DAZL RIP Mammalian Data (Mouse, Human)

SUPPLEMENTAL INFORMATION

Supplemental Information can be found online at <https://doi.org/10.1016/j.devcel.2020.11.008>.

ACKNOWLEDGMENTS

We would like to thank Virginia Bilanchone and Suzanne Sandmeyer for providing the anti-Ty3 VLP crude serum, Kayla Carpenter for RNA-sequencing prep, and S. Grace Herod for the *his3::pRIM4-OsTIR1::His3MX6* construct. We would like to thank Albert Serra Cardona and Zhiguo Zhang for help with Ndt80 ChIP. We would also like to thank Stephen Goff and members of the Berchowitz lab for valuable discussions and Jonathan Dworkin, Diana Ottoz, and Tanguy Lucas for critical reading of the manuscript. This research is supported by the Schaefer Research Scholars Program, the Hirschl Family Trust, NIH grant R35 GM124633-01 to L.E.B., MRC University Unit grant MC_UU_00007/6 to I.R.A., Agence Nationale de la Recherche grant ANR-16-CE12-0019 to G.L. and National Institutes of Health DP2 AG055946-1250 01 to E.Ü.; Finally, we would like to thank Harmit Malik who suggested an idea to L.E.B. that provided the motivation to begin this project.

AUTHOR CONTRIBUTIONS

L.E.B. and R.L. conceived of the study. L.E.B. and R.L. designed the molecular biology and yeast computational experiments. I.R.A. designed and analyzed the mammalian computational biology experiments. R.L. led the experimental procedures. R.L., A.D., G.D., S.B., H.A., E.U., A.H., and L.E.B. built strains, performed experiments, and analyzed the data. G.L., J.-X.Y., and M.D.C. screened the wild yeast strains for sporulation efficiency and estimated Ty count. L.E.B. and R.L. wrote the paper with input from all authors. The manuscript was edited by I.R.A., E.U., and G.L.

DECLARATION OF INTERESTS

STAR★METHODS

KEY RESOURCES TABLE

REAGENT or RESOURCE	SOURCE	IDENTIFIER
Antibodies		
α -HA.11 Clone:16B12 (mouse)	BioLegend	Cat# 901514
α -Pgk1 (Phosphoglycerate Kinase monoclonal) (mouse)	Novex (Life Technologies)	Part# 459250
α -v5 monoclonal (mouse)	Invitrogen	Cat# 46-0705
α -FLAG (rabbit)	Sigma-Aldrich	Cat# F7425
α -VLP (Ty3) crude serum (rabbit)	Sandmeyer lab (UC Irvine)	α -VLP (Ty3) crude serum
α -VLP (Ty3) affinity purified antibody, using <i>E. coli</i> produced Gag3 protein	This study	α -VLP (Ty3) affinity purified antibody
α -mouse HRP-conjugated secondary	GE Healthcare	Cat# NA931-1ML
α -rabbit HRP-conjugated secondary	GE Healthcare	Cat# NA934V
α -V5-coupled agarose	Sigma-Aldrich	Cat# A7345-1ml
Rat α -tubulin alpha	Bio-Rad	Cat# MCA77G
α -rat-FITC	Invitrogen	Cat# 31629
Chemicals, Peptides, and Recombinant Proteins		
Halt Protease Inhibitor	ThermoFisher	Cat# 1861279
ProlongGold anti-fade reagent w/ DAPI	Invitrogen	Cat# P36935
β -Estradiol	Sigma-Aldrich	Cat# E8875
MG-132	Cayman Chemical	Cat# 10012628
Auxin (indole-3-acetic acid)	Sigma-Aldrich	Cat# 12886-25G
α -factor mating pheromone	Genscript	Cat# RP01002
Acid-washed glass beads, 425-600 μ m	Sigma-Aldrich	Cat# G8772-500G
0.5mm dia Zirconia/silica beads	BioSpec Products	Cat# 11079105Z
Chelex resin	Bio-Rad	Cat# 1422832
Hybond-N+ membrane	GE Healthcare	Prod# RPN203B
10% Criterion TGX Precast Midi Protein Gel, 26 well, 15 μ l	Bio-Rad	Cat# 5671035
Trans-blot turbo transfer kits (Nitrocellulose)	Bio-Rad	Cat# 1704271
Illustra Probequant Columns	GE Healthcare	Prod# 28903408
Critical Commercial Assays		
AminoLink Plus Immobilization kit	Thermo Scientific	Cat# 44894
Amersham MegaPrime DNA Labeling Kit	GE Healthcare	Prod# RPN1604
Minelute kit	Qiagen	Cat# 28004
Accel-NGS 1S plus DNA library kit	Swift Biosciences	Cat# 10096
TruSeq Stranded Total Rna Kit	Illumina	Cat# RS-122-2302

RESOURCE AVAILABILITY

Lead Contact

Further information and requests for resources and reagents should be directed to and will be fulfilled by the Lead Contact, Luke E. Berchowitz (leb2210@cumc.columbia.edu).

Materials Availability

All strains and reagents used in this study are available upon request.

Data and Code Availability

The accession number for the RNA sequencing and ChIP sequencing dataset generated during this study is EBI ENA / NCBI Bio-Project: PRJNA669383 (<https://www.ncbi.nlm.nih.gov/bioproject/?term=PRJNA669383>; <https://www.ebi.ac.uk/ena/browser/view/PRJNA669383>).

Custom code and algorithms are available upon request.

EXPERIMENTAL MODEL AND SUBJECT DETAILS

Yeast Strains and Constructs

Lab strains are described in Table S1, and wild strains in Table S2. Strains were constructed by crossing and/or using the PCR-based method described in (Longtine et al., 1998) using the SK1 genome reference and annotation from (Yue et al., 2017). PCR and fusion PCR involved templates pFA6a-kanMX6 and pFA6a-His3MX6 (Longtine et al., 1998) and pUB976 (Sawyer et al., 2019). Seamless deletion of Ty3 was introduced by pop-in pop-out procedure as described in (Storici et al., 2001). The origins of all constructs are listed in the Key Resources Table (this study, or (Benjamin et al., 2003; Berchowitz et al., 2013, 2015; Carlile and Amon, 2008; Carpenter et al., 2018; Torres et al., 2007)).

METHOD DETAILS

Yeast Growth and Sporulation Conditions

All yeast strains were grown at 30° C. For sporulation of lab strains, strains were pulled from -80° C stock and grown on YPG (3% glycerol) plates overnight, were then transferred to YPD 4% (YPD + 4% glucose) plates for 24 h, were then grown to saturation in YPD for 24 h, diluted in BYTA (1% yeast extract, 2% tryptone, 1% potassium acetate, 50 mM potassium phthalate) to OD₆₀₀ = 0.3 and grown overnight. Cells were washed with water, resuspended in sporulation medium (0.3% potassium acetate [pH 7.0], 0.02% raffinose) to OD₆₀₀ = 1.8. Following inoculation into sporulation medium, cells were incubated with vigorous shaking (t = 0 h). For Rim4-deg strain, at t = 5 h, auxin (indole-3-acetic acid, Sigma) was added to a final concentration of 1 mM in order to induce degradation of Rim4. For *pdr5* mutant strain, proteasome inhibitor MG-132 was added at 6 h to 50 μM. For *NDT80-IN* (Benjamin et al., 2003) strains, at t = 6 h, β-estradiol was added to a final concentration of 1 μM (5 mM stock in ethanol, Sigma E2758-1G) to induce expression of *NDT80* from the *GAL1-10* promoter by activating the Gal4.ER fusion protein. For sporulation of wild strains, the procedure was essentially the same with the

exception that if tetrads were already observed after overnight on YPG plates, they were pulled again from -80°C directly on YPD 4%, and the protocol was continued from there. Time points were taken for Western and Northern blot analysis and immunofluorescence/DAPI as indicated.

For mitotic Ndt80/Sum1 experiments, strains were grown overnight in YPG (glucose in YPD would inhibit the *GAL1-10* promoter driving *NDT80*) and diluted to $\text{OD}_{600}=0.3$. Following transfer to fresh YPG medium, cells were incubated with vigorous shaking for 3 h. Then auxin (indole-3-acetic acid, Sigma) was added ($t=0\text{h}$) to a final concentration of 1 mM in order to induce degradation of Sum1. After 1 hour, β -estradiol was added to a final concentration of 1 μM (5 mM stock in ethanol, Sigma E2758-1G) to induce expression of *NDT80* from the *GAL1-10* promoter by activating the Gal4.ER fusion protein. Time points were taken for Western and Northern blot analysis as indicated (collected volumes were adjusted to the OD_{600} at each time point).

For pheromone exposure experiments, strains were grown overnight in YPD and diluted to $\text{OD}_{600}=0.2$. Following transfer to fresh YPD medium, cells were incubated with vigorous shaking for 3 h. Cells were pelleted and resuspended at an OD_{600} of 0.36 ($t=0\text{h}$), then α -factor (Genscript) was added to a final concentration of 0.8 $\mu\text{g}/\text{mL}$ (0.5 μM , “+”) or 16 $\mu\text{g}/\text{mL}$ (10 μM , “++”) in order to induce Ty3 activation. Time points were taken for Western and Northern blot analysis as indicated (collected volumes were adjusted to the OD_{600} at each time point).

Meiotic Progression Analysis

Cells were fixed in 3.7% formaldehyde. For analysis of nuclear divisions and spindle visualization, indirect immunofluorescence was performed as in (Carpenter et al., 2018) with minor modifications. To visualize spindles, we used rat anti-tubulin antibody (Bio-Rad) at a dilution of 1:200, and anti-rat-FITC antibody (Invitrogen) at a dilution of 1:200. Immunofluorescence samples were mounted in ProLongGold (Invitrogen) that included DAPI. Acquisition of images was conducted using a DeltaVision microscope (GE Healthcare). Spindle morphologies ($n=100$ cells per time point) were classified as in (Lee and Amon, 2001). Briefly, Metaphase I cells were defined as cells with a single DAPI mass spanned by a short, thick, bipolar, meiotic spindle. Anaphase I cells were defined as cells with two distinct (though not always separated) DAPI masses, and a single long spindle that spans both DAPI masses. Metaphase II cells were defined as cells with two separate DAPI masses with each spanned by a bipolar, short, thick, meiotic spindle. Anaphase II cells were defined as cells with four distinct (though not always separated) DAPI masses with two long spindles. Then, these four categories of cells were grouped under the label “cells in meiotic divisions”.

For analysis of nuclear divisions only, cells were washed once with 100 mM phosphate, 1.2 M sorbitol buffer [pH 7.5], permeabilized with 1% Triton X-100 and stained with 0.05 $\mu\text{g}/\text{ml}$ DAPI.

Northern Blot Analysis

Samples were prepared by snap freezing the pellet of 7.2 OD_{600} units of cells, and total RNA was isolated using a (400 μL : 400 μL) mixture of TES buffer (10 mM Tris [pH 7.5], 10 mM EDTA, 0.5% SDS) and acid phenol: chloroform 5: 1 (Ambion) with zirconia/silica beads (BioSpec) while shaking at 1400 rpm (Thermomixer, Eppendorf) at 65°C for 30 min. After centrifugation at 16,000 g for 5 min, the supernatant was ethanol precipitated at -20°C overnight (1 ml 100% ethanol and 40 μL 3M sodium acetate [pH 5.5]), centrifuged at 16,000 g for 20 min, washed in 80% ethanol, dried, and resuspended in DEPC-treated water. For wild strains, RNA extraction required two chloroform purification. 5 μg of RNA was denatured at 55°C for 15 min in 50% formamide, 18.3% formaldehyde, and 5% MOPS and was resolved on a denaturing agarose gel (1.9% agarose, 3.7% formaldehyde, 1x MOPS buffer) for 2.5 hours at 80 V. RNA was transferred to a Hybond-N+ membrane (GE Healthcare) by capillary transfer in 10x SSC (1.5 M NaCl, 0.15 M trisodium citrate dihydrate, [pH 7]). The membrane was stained with methylene blue, incubated in hybridization Buffer (0.25 M Na-Phosphate [pH 7.2], 0.25 M NaCl, 1 mM EDTA, 7% SDS, and 5% dextran sulfate) at 65°C and probed with ^{32}P -labeled PCR products prepared via Amersham Megaprime DNA labeling kit (GE Healthcare) and Illustra ProbeQuant columns (GE Healthcare), transferred to a phosphor screen, and imaged on a Typhoon Trio variable mode imager (Amersham).

To observe Ty3 dimers we conducted semi-denaturing Northern blot analysis (adapted from (Nymark-McMahon et al., 2002)). Briefly, the procedure is as above except we omitted formamide in the denaturing mix and incubated 15 minutes at 30°C .

Yeast RNA Sequencing and Sequencing Analysis

Briefly, poly-A pull-down was used to enrich mRNAs from total RNA samples and proceed on library preparation by using Illumina TruSeq RNA prep kit. Libraries were sequenced using single-end sequencing (100 bp) in multiplex using Illumina HiSeq4000 at Columbia Genome Center. RTA (Illumina) was used for base calling and bcl2fastq2 (version 2.17) for converting BCL to fastq format, coupled with adaptor trimming. Sequencing reads were mapped onto SK1 genome reference (Yue et al., 2017) using STAR (Dobin et al., 2013) with the following parameters: Multiple alignments allowed: 500 (takes into account the number solo-LTR loci in the genome); Multiple alignment retained: 1; Order of multiple alignments: Random (–outFilterMultimapNmax 500 –outSAMmultNmax 1 –outMultimapperOrder Random –outFilterScoreMinOverLread 0.3 –outFilterMatchNminOverLread 0.1 –seedSearchStartLmax 20 –seedSearchStartLmaxOverLread 0.2) while other parameters were set to defaults. Reads count were scaled by CPM (count per millions) and visualized using Ving software (Descrimes et al., 2015).

Immunoblot Analysis

The pellet of 7.2 OD_{600} units of cells was resuspended in 5% TCA, incubated overnight at 4°C , washed with acetone, and dried. Cells were broken using 50 μL acid-washed glass beads (Sigma), 100 μL lysis Buffer (10 mM Tris-HCl [pH 11], 1 mM EDTA [pH 8], 2.75 mM

DTT, Halt protease inhibitors (Thermo Fisher), and a 45 sec process in a FastPrep-24 (MP Biomedicals) at max speed. 50 μ L Loading Buffer (9% SDS, 0.75 mM Bromophenol blue, 187.5 mM Tris-HCl [pH 6.8], 30% glycerol, and 810 mM β -mercaptoethanol) was added, samples were heated at 100°C for 5 mins, and centrifuged 5 mins at 20,000 g. Polyacrylamide gels (precast 10% Criterion TGX Precast Midi Protein Gel 26 wells, Bio-Rad) were run on a midi gel system (Criterion Vertical Electrophoresis Cell, Bio-Rad) with SDS Running Buffer (190 mM glycine, 25 mM Trizma base, 3.5 mM, 1% SDS), with 4 μ L sample per well. They were transferred using a semi-dry transfer apparatus (Trans-Blot Turbo Transfer System, Bio-Rad) to a nitrocellulose membrane (Trans-blot turbo transfer kits – Nitrocellulose, Bio-Rad), and stained in Ponceau.

α -VLP antibody was purified from α -VLP (Ty3) crude serum (gift from Sandmeyer lab), using Gag3 protein produced from pLZL2422 (Larsen et al., 2008) coupled to an AminoLink column (Thermo).

Antibodies were prepared in 1X TBST with 1% milk 1% BSA. Primary antibodies were used at the following concentrations: α -VLP (purified from α -VLP (Ty3) crude serum, gift from Sandmeyer lab) 0.1 μ g/mL, α -HA.11 1:1,000 (BioLegend), α -V5 1:2,000 (Invitrogen), α -FLAG (Sigma) 1:800, α -Pgk1 1:20,000 (Novex). α -mouse or α -rabbit HRP-conjugated secondary antibodies (GE Healthcare) were used.

Ndt80 ChIP-seq

NDT80-3V5 and no tag control cells were sporulated at 30°C. Cells were fixed in 1% formaldehyde for 15 minutes at room temperature and quenched with 0.1 M glycine (final concentration). Samples were prepared by snap freezing the pellet of 20 OD₆₀₀ units of cells. Cells were resuspended in 0.4 ml lysis buffer (50 mM HEPES/KOH pH [7.5], 140 mM NaCl, 1 mM EDTA, 1% Triton-X, 0.1 % Na-deoxycholate, 1 mM PMSF) lysed with zirconia/silica beads (BioSpec) in a FastPrep homogenizer. The homogenate was centrifuged at 2,500 rpm for 1 minute and the supernatant was discarded. The pellet was resuspended in 0.25 ml lysis buffer and sonicated (15 sec on, 30 sec off, 10 cycles). Lysate was centrifuged at 10,000 g for 5 minutes at 4°C and supernatant was transferred to a new tube. 50 μ L was taken for DNA input sample and the remaining sample was processed for ChIP.

Ndt80-DNA complexes were immunopurified using anti V5 agarose beads (Sigma) for 1 h at 4°C. Beads were washed and cross-links were reversed using Chelex resin (Bio-Rad). Elution was carried out by boiling samples for 10 minutes followed by Proteinase K digestion (1 mg/ml 30 min at 55°C). Beads were boiled again for 10 minutes and the eluate was collected and purified/concentrated using a Qiagen Minelute kit. Sequencing libraries were prepared from the eluate using an Accel-NGS 1S plus (Swift Biosciences) per the manufacturer's protocol. Libraries were sequenced using paired-end sequencing (2x100 bp) in multiplex using NextSeq 550.

QUANTIFICATION AND STATISTICAL ANALYSIS

Immunoblot and Northern blot were quantified using FIJI software (Schindelin et al., 2012). Signal intensity was normalized to a loading control (Pgk1 for immunoblots, 25S rRNA for Northern blots). Values were multiplied by an arbitrary scaling factor, which was held constant within each figure panel for each technique. Statistical significance was determined by Student's T-test or Z-test statistic as indicated. Number of biological replicates is indicated in figure legends where applicable.

Statistical Analysis for Ndt80 Binding Site Enrichment Upstream Ty3 Insertions

Data analysis was performed using the R project for statistical computing version 3.6.1 (<https://www.r-project.org>) and RStudio version 1.1.383 (<https://www.rstudio.com>), utilizing the following packages: dplyr, tidyr, stringr, ggplot2, plotly, tools, boot, Biostrings, GenomicRanges, janitor, seqinr, BiocManager, TFBSTools. Briefly, yeast genomes were downloaded from (Yue et al., 2017) and Ndt80 binding sites (defined as CAAAA by (Nocedal et al., 2017)) were identified. Then the positions of Ndt80 binding site upstream Ty3 elements (full-length or solo-LTRs) were recorded. For Ndt80 target genes and non-target genes in SK1, the same process was applied, using the SK1 reference genome and annotation from (Nocedal et al., 2017). For bootstrap, the R function `sample_n` was used to take samples with replacements. Then the data was visualized using 50 bp long non-overlapping bins. We used the distribution of outlier boundaries for each bootstrap experiment to identify region of significant difference in Ndt80 binding site enrichment.

Analysis of Yeast ChIPseq Data

Reads were trimmed of their adaptors using cutadapt (Martin, 2011) and were aligned to the *S. cerevisiae* SK1 genome (Yue et al., 2017) using Bowtie2 version 2.3.4 (Langmead and Salzberg, 2012). Alignments were filtered using samtools v1.6 (Li et al., 2009) (samtools view -f 2 -F 1804 -q 30), and PCR duplicates were filtered out using Picard tool MarkDuplicates v2.23.3 (Broad Institute). Deeptools bamcoverage (Ramírez et al., 2016) was used to generate a coverage track of number of reads per bp after reads were extended to their mates, to reflect the actual fragment length. Coverage was then normalized using a script detailed in (De Muyt et al., 2018): upon the assumptions that for a transcription factor, peaks are expected to be narrow, they are expected to fall in the top outliers of the coverage distribution, while the background regions are expected to fall in the bulk of the distribution, between Q1-1.5IQR and Q3+1.5IQR. Hence, for untagged immunoprecipitate (UIP), the coverage was divided by the average read count in non-null and non-outlier positions, while for tagged immunoprecipitate (IP), the coverage was divided by the average read count in non-null and non-outlier positions and multiplied by the average read count of the same set of positions in the normalized UIP. Normalized profiles were used for peak detection using bpeaks v1.2 (Merhej et al., 2014) using as thresholds: T1: $IP > (Q3_{UIP} + 1.5IQR_{UIP}) * \text{mean}(IP)$, T2: $UIP > (Q1_{UIP} - 1.5IQR_{UIP}) * \text{mean}(UIP)$, T3: $\log_2 FC > 0.5$, and T4: $(\log_2(IP) + 1) + (\log_2(control) + 1) / 2 > 0$. For visualization on IGV (Thorvaldsdóttir et al., 2013), normalized UIP profiles were subtracted to their corresponding normalized IP profiles using Deeptools bigwigCompare (Ramírez et al., 2016).

Analysis of Mammalian RNAseq Data (Mouse, Opossum)

RNAseq from enriched populations of adult mouse testicular cell types (Soumillon et al., 2013) was downloaded from EBI ENA:PRJNA187158 (<https://www.ebi.ac.uk/ena>). Reads were trimmed to remove adapter sequences (stringency 5 –length 20) using TrimGalore 0.4.1 (<https://github.com/FelixKrueger/TrimGalore>) then aligned to the mm10 reference assembly of the mouse genome with Tophat v2.1.0 (Kim et al., 2013) (command line options -g 1 –no-coverage-search –b2-sensitive) using the GencodeBasic VM18 transcriptome as a transcriptome index (Frankish et al., 2019). Accepted hits from Tophat were filtered with samtools v1.6 (Li et al., 2009) to remove unmapped reads and non-primary alignments. For locus-specific analysis, uniquely mapping reads were selected by removing reads with a quality score below 5. Reads overlapping Repeatmasker-annotated loci in the mouse genome were counted for each repeat locus, and aggregated at the level of the repeat name (repName). EdgeR (Robinson et al., 2010) was then used to normalize the counts per million mapped fragments in each sample using trimmed means. CPMs were converted to fragments per kilobase of transcript per million mapped reads (FPKM) by dividing CPM by the length of the repeat locus for locus-specific analysis, or by the mean length of repeat loci annotated with that repeat name for repName-level analysis.

RNAseq for P14 *Mybl1* testes (Zhou et al., 2017) and *Stra8* preleptotene spermatocytes (Kojima et al., 2019) were downloaded from EBI ENA:PRJNA476515, PRJNA476515, trimmed and mapped to mm10 as described above. The paired end *Mybl1* data was mapped using mate inner distance and mate standard deviations of 30 and 68 respectively. Accepted hits from Tophat were filtered as described above and uniquely mapping reads falling within GencodeBasic VM18 genes counted using htseq-count v0.11.2 (Anders et al., 2015) in intersection-nonempty mode. The ENSMUST00000174651.1 transcript in the GencodeBasic VM18 annotation, which appears to be a *Moap1* transcript originating from an alternative upstream promoter, was manually re-assigned from the RP24-234J3.3 gene to *Moap1* to circumvent ambiguity in htseq-count assigning reads to *Moap1*. EdgeR was used to normalize the counts per million mapped fragments in each sample using trimmed means, data for genes of interest (*Moap1*, *Pnma1*) selected from the dataset, and Student's t-test used to assess statistical significance between *Mybl1*^{+/–} and *Mybl1*^{–/–} P14 testis samples, or between *Stra8*^{+/–} highSTRA8 preleptotene spermatocyte and *Stra8*^{–/–} preleptotene spermatocyte samples.

FPKMs from RNA-seq for opossum from purified spermatocyte/spermatid and multitissue (Lesch et al., 2016; Marin et al., 2017) were downloaded from NCBI GEO: GSE68507, GSE97367.

Analysis of Mammalian ChIPseq Data (Mouse)

Mybl1 and *Stra8* ChIPseq data from mouse testes (Kojima et al., 2019; Zhou et al., 2017) were downloaded from EBI ENA:PRJNA321732, PRJNA476515, trimmed as described for RNAseq data, then aligned to the mm10 assembly of the mouse genome using Bowtie v2.2.6 (Langmead and Salzberg, 2012). Bowtie output was filtered to remove PCR duplicates marked by PicardTools v2.17.11 (<http://broadinstitute.github.io/picard/>), and to remove reads mapping to mitochondrial or blacklisted regions of the genome (<https://www.encodeproject.org/files/ENCFF023CZC/>), unmapped reads, non-primary alignments and reads with a quality score below 5. Bedtools (Quinlan and Hall, 2010) was used to convert the Bowtie alignments to ENCODE tagAlign format, and MACS v2.1.1 (Zhang et al., 2008) used to call peaks on pooled ChIP samples relative to pooled input controls using default settings (q < 0.05) and to generate Bedgraphs showing fold enrichment in pooled ChIP relative to input samples. For *Stra8* ChIPseq, the fold-enrichment for anti-FLAG ChIP in control wild-type samples was then subtracted from the fold-enrichment for the anti-FLAG ChIP in experimental *Stra8*^{FLAG/FLAG} samples. For *Mybl1* ChIPseq, anti-*Mybl1* ChIPseq from *Mybl1*^{+/–} testes was compared to *Mybl1*^{+/–} input controls. ChIPseq bedgraphs and peak co-ordinates were visualised using Gviz (Hahne and Ivanek, 2016). Distances from Repeatmasker-annotated MamGyp-int loci and GencodeBasic VM18 genes overlapping those loci to the nearest *Stra8* and *Mybl1* ChIPseq peaks were determined using BEDtools v2.26.0 (Quinlan and Hall, 2010).

Analysis of Dazl CLIP and DAZL RIP Mammalian Data (Mouse, Human)

Dazl CLIP tag locations from mouse testes (Zagore et al., 2018) were downloaded from GEO:GSE108181 and the genomic co-ordinates lifted over from mm9 to mm10 using the UCSC liftOver tool (Haeussler et al., 2019). DAZL RIP data from human ovaries (Rosario et al., 2017) (available in EBI ENA:PRJNA321858) was trimmed and aligned to the hg38 assembly of the human genome as described for the RNAseq data using a mate inner distance of 260 and mate standard deviation of 110. Tophat output was filtered, then reads in genes or repeats counted using htseq-count or BEDTools and normalized in EdgeR using the total number of mapped fragments as the library size as described for the RNAseq data. To assess *MOAP1* and *PNMA1* behaviour in the htseq-count data, EdgeR, low abundance genes were removed using *filterByExpr(count=15, min.count=10)*, *glmLRT* used to determine differentially abundant genes in a paired experimental design, *MOAP1* and *PNMA1* data extracted from the resulting DGEList object. and false discovery rate used to correct p-values for multiple-testing. To determine enriched retrotransposon sequences in the anti-DAZL samples, repName-aggregated repeat count data for retrotransposons (LINE, SINE and LTR repeat classes) were selected then low abundance retrotransposons removed using *filterByExpr(count=15, min.count=10)*. *glmLRT* was used to determine differentially abundant retrotransposons in a paired experimental design, and false discovery rate used to correct p-values for multiple-testing. Data for retrotransposons belonging to the Gypsy repeat family were plotted.
