Abstract

During recent excavations in the third-millennium BC plundered graveyard of Mahtoutabad, next to Konar Sandal (Kerman, Iran), the authors excavated layers with Uruk-related ceramics. The types include bevel-rim bowls, flowerpots, low-sided trays, nose-lugged jars and other types previously encountered at several other contemporary sites in highland Iran. This new material is presented here with some preliminary comments on the general picture of the Uruk-related sites and pottery assemblages across the Iranian plateau of the mid- and late fourth millennium BC. We suggest that the related elements of the material culture of these contexts should be considered as open single questions, rather than as part of a monolithic cultural pattern awash with demanding historical or even ethnic implications.

Keywords

Mahtoutabad site; Konar Sandal; Halil Rud culture; Uruk phenomenon on the Iranian plateau; ancient ceramic technology

I. INTRODUCTION

The ceramic assemblage we present in this paper comes from a single trench dug in a small, peripheral site of the Konar Sandal site complex, which lies near the present town of Jiroft in the Kerman province of Iran, and is best known for the recent ruinous pilferage of its third-millennium BC graveyards. Although the whereabouts and archaeological contexts of the original occupation from which this pottery originated are still unknown, the assemblage represents, so far, the easternmost evidence of the Uruk phenomenon across the Iranian plateau. The deposits that were excavated are clearly secondary but they are coherent from a chronological and cultural viewpoint, and will help us better to evaluate the assemblages of Tal-i Iblis, where stratigraphy was not fully controlled, and those of Tepe Yahya, with its much-discussed associations. We believe that the holistic evaluation of these three sites (Tal-i Iblis IV–VI; Tepe Yahya IVC; Mahtoutabad III) will eventually be useful to build up a new frame of reference for the Kerman region in the mid- to late fourth millennium BC.

The site of Mahtoutabad (28°27'20"N; 57°47'26"E) lies about 1.4 km south-east of the Konar Sandal North Tepe and 1.3 km north-east of the Konar Sandal South early urban complex (Figs. 1 and 2).¹ The site, plundered with other local graveyards in 2001 (Fig. 3), was investigated as part of a rescue operation carried out between 2006 and 2009. The first campaign took place in January–February 2006, under the direction of Y. Madjidzadeh. The graveyard (period Mahtoutabad IV) had been used in the second half of the third millennium BC on top and beside a natural bank at the edge of the bed of the Halil River (Fig. 4). At the time the bank must have risen 1–2 m higher than the surrounding plain, and thus protected the graves from the most immediate risks of flooding, until the area was sealed by thick silty alluvial layers, presumably in the historical period. Following a major flood in 2001, the current bed of the Halil finally cut through the burial area along its right bank on the west,² exposing the graves and their rich furnishings. A small number of other graves were plundered on the eastern side of the

present bank. Without this flood and the destruction led by the plunderers, the underlying late prehistoric settlements would never have been found, because no artificial elevation or scatter of artefacts was visible on the currently cultivated surfaces.

Our main operation, Trench I, enabled us to recover large amounts of artefacts discarded by the illegal diggers that date to the graves of the second half of the third millennium BC (Mahtoutabad IV). While surveying the eastern fringe of the main burial area along the current western bank of the Halil, where illegal digs had been systematic and intensive, we found clustered fragments of bevel-rim bowls (hereafter BRBs) scattered on the surface of the excavation dumps and in the fillings of the robbers' trenches. Other sherds of the same type were still embedded in layers of ceramics and other cultural materials exposed by the vertical pits' sections. We excavated this site under the label of Trench V. The ceramics were comparable to various mid- to late fourth-millennium BC assemblages previously known in other sites of the Iranian plateau, and

the relative phase of occupation was named Mahtoutabad III. Trench I also revealed, below the level of the third-millennium BC graves, a thick deposit of Iblis IV-related ceramics, suggesting that the area had been settled in the early to mid-fourth millennium BC (Mahtoutabad II; Desset, Vidale and Alidadi Soleimani, ongoing research).

The earliest local settlement (Mahtoutabad I) was reached at a depth of about 4 m below the surface in Trench I. Here, we unearthed half of a large oval hut with post holes on the virgin soil, associated to a distinctive polychrome pottery. Four calibrated radiocarbon-AMS dates place this period between *c.* 4200 and 3700 BC.³ Thus, although deeply disturbed, the site of Mahtoutabad revealed an important sequence of occupation stretching for much of the fourth millennium BC, which allows a first glance at the material assemblage of formative stages of the local Halil Rud cultural assemblage.

II. STRATIGRAPHY OF TRENCH V AND SITE DEPOSITIONAL PROCESSES

The Uruk-related materials related to period Mahtoutabad III, which were found in Trench V, came from horizontal or slightly sloping layers of clayey silt beside the Halil Rud. No architectural feature was recognised. Trench V (Figs. 4 and 5) was originally planned as a strip measuring 9.5×4.5 m, the longer side oriented west–east (i.e. orthogonal to the nearby riverbank). Its main purpose was to excavate whatever was left of the Mahtoutabad III layers. In fact, we uncovered patches of an extensive surface almost completely destroyed by the robbers who, having found dozens of complete vessels, were hoping to locate other graves. The undisturbed deposits were small residual strips, from c. 0.50–1 m wide, surviving among the looting pits (Figs. 6, 7 and 8). The diggers had, typically, also excavated below the archaeological layers, with horizontal tunnels connecting one pit to another. Thus, defining the formation processes of the Mahtoutabad III layers at the site was a painstaking and rather frustrating process, but in spite of the damage, it was possible to find secure stratigraphic contexts.

In January–February 2009, our last season at Mahtoutabad, Trench V was enlarged laterally and deepened under the co-direction of M. Vidale and N. Alidadi Soleimani, mainly to collect a larger sample of the ceramics of this occupation. On the western side of the exposed area we found several complete vessels, mainly BRBs, and many fragments of fired plaster and fired jar sealing fragments, all in a primary context of deposition. To the east (i.e. towards the present riverbed) the cultural materials had been transported, scattered and finally deposited by natural processes (layer TV-9). The coherence of the ceramic assemblage, free from earlier or later materials, suggests that the Trench V deposits belong to a single phase of occupation, perhaps an open area at the edge of a nearby fourth-millennium BC settlement.

The stratigraphy of Trench V can be analytically described with reference to the eastern side of the northern section (Figs. 5 and 9). The layer descriptions are as follows:

- Layer TV-1: debris from the 2001 looting pits in a heap collapsing eastwards. Loose silty sand with clay lumps and silty clay sods of variable colours.
- Layer TV-2: a heap of pure loose greyish-brown sand (2.5Y 5/2), in secondary context of deposition, excavated from the thick deposits of sand of the 2001 flood and dumped beside the pits.
- Layer TV-3: slightly sandy silt abundantly mottled with whitish (carbonatic) inclusions. It has a prismatic structure and strong vertical cracks made by roots and enhanced by the strong desiccation of the local bank (brown to pale brown, 10 YR 6.3–10 YR 5.3).
- Layer TV-4: alluvial sandy silt. Inhomogeneous, made of dark (dark greyish brown, 10 YR 4.2) and lighter (pale brown, 10 YR 6.3) matrix components. It included pebbles, fired clay particles and a small number of potsherds (types characteristic of Mahtoutabad II and III).
- Layer TV-5: an inhomogeneous horizon of slightly clayey silt, with a greater amount of isolated calcareous inclusions (up to 1 cm in diameter, white, 10 YR 8.2). The matrix is distinguished by a darker colour (dark greyish brown, 10 YR 4.2).
- Layer TV-6: slightly sandy silt (pale brown, 10 YR 6.3) free from any anthropic inclusion.
- Layers TV-7 and TV-8: two brown (10 YR 5/3) layers of massive alluvial silty clay, about 12–15 cm thick. These two layers are hard, compact and pure, and crack with vertical fissures. Between layers 6 and 7, 7 and 8 and 8 and 9, there are thin horizontal layers of an extremely fine clay or loess-like deposit, the colour of which (very light brown, 10 YR 7/3) sharply contrasts with layers 7, 8 and 9. TV-7 and 8 are probably decreasing energy flow deposits left on the riverbank by flood events, alternating with drought episodes corresponding to exposed sedimentary surfaces marked by thin aeolian deposits.
- TV-9: this thick alluvial layer of sandy silt (dark greyish brown, 10 YR 4.2) contained sizable quantities of large Mahtoutabad III (c. mid–late fourth-millennium BC) potsherds, rocks cracked by fire, a few animal bones and evidence of lithic industry and other cultural materials deposited across an extensive open-air surface. While the top of this alluvial layer hosts sherds in sub-horizontal settings, it also included larger fragments or complete vessels that were more chaotically arranged. This paper deals mainly with the material found in this layer.
- TV-10: another thick layer of pale brown (10 YR 6/3) clayey silt, apparently free from any anthropic inclusions. Its lower stratigraphic limit was not exposed.

Fig. 5. Mahtoutabad: (below) map of trench V (2007–2009); (above) northern stratigraphic section. (Image M. Vidale and F. Desset.)

Fig. 6. Mahtoutabad: a phase of the excavation, showing the excavated patches of undisturbed stratigraphy among the pits and tunnels dug by looters. (Image M. Vidale.)

Fig. 7. Mahtoutabad: excavating a complete bevel-rim bowl. (Image M. Vidale.)

Fig. 8. Mahtoutabad: a detail of the excavated deposit, with fragments of bevel-rim bowls, flowerpots, coarse low-sided trays, spouts and globular jars coming to light. (Image M. Vidale.)

Fig. 9. Mahtoutabad: detail of the main section of Trench V, showing the rhythmic alternation of flood deposit (darker) and interruptions of the sedimentation process marked by aeolian films (lighter-coloured layers). The ceramic assemblage discussed in this paper comes from the lowermost horizon (TV-9). (Image M. Vidale and F. Desset.)

In brief, the northern section of Trench V shows at least three flood events (layers 7, 8 and 9) each followed by dry events that were apparently short lasting. Then a higher energy flow deposited a sandy silt rather than a silty clay (layer 6) on the site, before a new fluvial erosion (layer 4) deposited a few tiny Mahtoutabad II–III sherds.

Unfortunately the total absence of carbonised material prevented any chance of absolute dating for these deposits. As far as the animal bones are concerned, previous attempts at using bones for dating the third-millennium BC graveyard have failed, possibly due to the effects of the local variations of the water table near the Halil Rud bank.

III. THE POTTERY

III.1. “Interregional” forms

Among the most recognisable forms found on the surface after the recent disturbances, within the illegal pits themselves or recovered later during the excavation, were a number of unpainted forms that were immediately visibly akin to material seen in other Uruk-related assemblages at sites in the western and central Iranian plateau and Khuzistan (BRBs, moulded; flowerpots, wheel-thrown; some types of small- and medium-sized jars, including bottles and vessels with down-turned shoulder spouts; a few restricted carinated containers with nose-like applied lugs and other forms; globular jars or pots with handles or lugs; coarse low-sided oval trays). All these types are well known and, with

34–35	-
36–37	2

some exceptions, have been consistently described and labelled in excavation reports. The same basic and standard names will be used here, and more detailed descriptions will be reserved for particular forms and variants, or to unusual vessels.

The mouth diameter of 158 BRBs and fragments (both from surface and excavated deposits) could be measured on the horizontal tangency plane, from the interior (Figs. 10, 11, 12 and 13). Admittedly, their mouth contour is so irregular that the exercise may be considered, at best, optimistic but Table 1 (where, because of this irregularity, the measurements come in 2-cm intervals) shows that the bulk of the BRBs had mouth diameters ranging from 18 to 25 cm, with a limited series of very small specimens between 14 and 17, and an equally limited group of larger vessels (large at the mouth from 26 to 37 cm). The smaller BRBs are often squat, while the largest ones tend to be quite tall, probably because the height was more variable than the other dimensions. Table 2 shows that the diameters at the base, when preserved, can be measured with more precision and vary primarily from 9 to 13 cm.

The importance of BRBs in the “contemporary” published assemblages is quite variable. For example, their frequency in the Mahtoutabad sample (*c.* 13%–14%, see below) cannot be compared with the enormous quantities reported at Chogha Mish.⁴ At Godin Tepe, BRBs are likely to represent around 20–30% of the pottery from Period VI.⁵ The frequency of BRBs

TABLE 2. Size of the bases of BRBs (reconstructed diameters).

Base (external) cm	Quantity
9 cm	11
10 cm	15
11 cm	21
12 cm	18
13 cm	10
14 cm	5
15 cm	2

at Mahtoutabad is slightly higher than in Arisman (9%),⁶ but six times higher than at Banesh period Tal-e Malyan (*c.* 2%).⁷ The Mahtoutabad frequency is also apparently much higher than in the IVC building and later levels at Tepe Yahya.⁸

In terms of size and form, the Mahtoutabad BRBs also show some differences to those from other sites. At Tepe Farukhabad, although the distribution of mouth diameters is somewhat similar to Mahtoutabad with very rare small specimens (up to 15 cm), equally rare larger ones (30–31 cm) and a norm between 16 and 23 cm, on average these containers are slightly smaller than those found at our site (*c.* 19.5 vs. 22 cm), and this is confirmed by the mean diameters of the bases (*c.* 8.3 cm vs. 11.3 cm). The BRBs published from Tepe Yahya are definitely smaller, and the main mouth diameters at Arisman vary from 14 to 20 cm.⁹ The taller BRB variety might also be on record at both sites.¹⁰ Moreover, the largest BRBs at Tepe Farukhabad, those published in the Chogha Mish

common form; the group, however, includes another four categories of small bowls.

⁹ Potts D.T. 2001: fig. 2.19.A, B; Helwing 2011a: 247, fig. 35, 201–203.

¹⁰ “Both a smaller and a taller variety have been discovered (at Tepe Yahya) which have parallels at Susa” (Lamberg-Karlovsky and Tosi 1973: 36; see Potts D.T. 1977: 28, n. 30). The Susa parallel is with a tall flowerpot published in Le Brun 1978a: fig. 34, 3, and should not be related to BRBs. The confusion between wheel-thrown flowerpots and tall moulded BRBs is present in other articles (e.g. Rothman and Badler 2011).

⁴ Delougaz and Kantor 1996: 50.

⁵ This approximate value is inferred from Rothman and Badler 2011: 86, when they report that at Godin Tepe Period VI, small bowls (< 24 cm) amount to about 58% of the total, and that within this group BRBs are the most

Fig. 13. Mahtoutabad: A group of bevel-rim bowls showing the formal and dimensional variability of the type. (Image M. Vidale.)

report¹¹ and one of the largest found in Arisman,¹² are all shallow rather than tall.¹³

Flowerpot fragments are not uncommon in the Mahtoutabad III collection (Fig. 14). They are tall and slender, with restricted string-cut bases and an overall flaring contour. The inner wall often shows the continuous spiral-like rill that indicates wheel throwing, and rims are slightly thickened and projected toward the inside of the mouth. The base material is a low-fired clay tempered with finer chaff particles, which is slipped red-orange. No complete specimen was found, and most flowerpots had bases 10–11 cm wide, with mouth diameters of 18–20 cm or more, and a height wavering around 25 cm or more. Vessels of this type have been recorded at Tepe Farukhabad, Tal-e Malyan and Tal-e Nurabad,¹⁴ but were not found at Chogha Mish, Godin Tepe, Arisman or Tepe Yahya. At Tepe Farukhabad, a more common variant of the same class of vessels, distinguished by a narrow and tapering solid base, which was also recorded at Tal-e Malyan but not at Mahtoutabad, was used in the most elaborate buildings.¹⁵

Figure 15 shows a group of different types of restricted vessels. The restricted jar shown in Figure

15.1 was distinguished by a short sub-vertical rim and sloping shoulder, and only resembles some specimens from Chogha Mish¹⁶ and the “Everted Collar Necked Jars” described at Godin Tepe.¹⁷

Figure 15.2 shows the distinctive neck of a type of bottle with a slender elongated body and a downward-bent spout on the shoulder. At Chogha Mish¹⁸ and other sites, these vessels are from 35 to more than 80 cm tall, about 15 cm wide and there is little doubt that they were used to transport, store and pour valuable liquids. The type is also reported at Tepe Farukhabad,¹⁹ Susa Acropole I, levels 18–17,²⁰ and Tepe Sialk IV.²¹ A small number of spouts of the same type were unearthed in the Oval complex of Godin Tepe, Period VI,²² but so far not at any other site in the Kerman region. The thick cone-shaped bottoms shown in Figure 15.5–6, which are distinguished by an extensive horizontal scraping caused by turning on the potter’s wheel, probably belong to the same elongated containers. The spouts shown in Figure 15.8, 10 and 11 might also have been detached from similar forms, or from the squatter pots and shorter restricted jars that are well illustrated in the Chogha Mish report.²³

Figure 15.3 shows the concave neck of a restricted jar. Although scarcely diagnostic, this fragment can

Medium-fine ware, sand-tempered, pale red (10 R 6/2). 10. Lot 22. Medium-fine ware, finely sand-tempered, pinkish grey (7.5 YR 7/2). 11. Lot 22. Medium-fine ware, pink (7.5 YR 7/4). 12. Trench V, TV-9. Medium-fine ware, pale brown (10 YR 6/3), with residues of a red pigment on the shoulder. The nose-lug was originally painted black. 13. Trench V, TV-9. Medium ware, sand-tempered, very pale brown (10 YR 7/4), painted very dark grey (2.5 Y 3/0). 14. Trench V, TV-9. Medium-coarse ware, sand-tempered, brownish yellow (10 YR 6/6), slipped red (2.5 YR 5/8). (Image M. Vidale and F. Desset.)

be compared to a very similar specimen from Tepe Yahya, as well as with a couple of restricted jars at Arisman, and possibly also with a small decorated jar found at Chogha Mish.²⁴

Figure 15.4 shows a fine miniature jar made on the potter's wheel and covered with a bright red slip. It may be compared with variable confidence with some small jars found at Chogha Mish²⁵ where this form was also reproduced in limestone,²⁶ suggesting that these vessels contained cosmetics or other valuable substances.

Figure 15.9 shows a rim spout distinguished by a slightly curved profile and a V-shaped section. The only vessel with this type of spout with a preserved form is illustrated in Figure 15.7—a small pear-shaped jar. Note how the spout is set on the rim with a left twist, and not symmetrically, which is a feature shared by the other identical spouts recovered in the Mahtoutabad III assemblage. While a similar form was found at Tal-e Malyan, some identical spouts were found in the nearby sites of Tal-e Kureh,²⁷ in IVC levels at Tepe Yahya,²⁸ at Tal-i Iblis IV²⁹ and at Tol-e Nurabad Phase A9.³⁰ Small restricted jars with similar rim spouts and perhaps comparable functions were found at Arisman, but the walls are much thicker and the body in the majority of the cases is distinctively biconical.³¹ The same type was identified in late fourth-millennium BC contexts at Tepe Sialk IV.³²

The three fragments of nose-lugged jars shown in Figure 15.12–14 and Figure 16 bring us immediately westwards to Susiana. The Figure 15.12 example shows a fine medium-sized jar with thin walls, a strongly carinated shoulder and probably a cylindrical neck, with remnants of nose lugs and the attachment of a strap vertical handle. The shoulder has faint traces of a red wash above and below the ridge, while the nose lug seems to have been painted black. The little that remains is reminiscent of some vessels in the

ceramic assemblage of Chogha Mish,³³ which also appear in very elaborate versions. Delougaz and Kantor compared the type to finds from Habuba Kabira, Tello, Tal-e Malyan and Susa Acropole I.17B, where the vessel was also carved in stone.³⁴ The vessel shown in Figure 15.13 is even smaller, but can be ascribed to a small- to medium-sized sub-globular jar with nose lugs on the shoulder and a painted frieze of hatched triangles running at the same height. There are similar specimens from Chogha Mish although the decoration is incised rather than painted.³⁵ At Tepe Farukhabad, however, a four nose-lugged sub-globular jar with the same painted frieze of hatched triangles looks exactly like the Mahtoutabad specimen.³⁶ The third fragment, shown in Figure 15.14, belongs to a small biconical squat-necked jar with four nose lugs and a single upraised flat handle. In this case the comparison with Chogha Mish is even more faithful.³⁷

The painted necked carinated jars found in late fourth-millennium BC contexts at Tepe Yahya³⁸ share the nose-lugs on the shoulder, but have more restricted contours, and are painted in broad bands of superimposed friezes below the shoulder, which is left plain. At Arisman, while forms and decorative patterns seem closer to western models, some of the friezes, as at Tepe Yahya, run along the maximum expanse of the jars rather than on the shoulder.³⁹ At Godin Tepe, while the majority of the four-lugged necked jars look identical to those of Chogha Mish in that they are a decoration with friezes of triangles running on the shoulder between the nose-lugs, at least one is painted on a red slip and resembles the Tepe Yahya and Arisman specimens, which have a broad geometric band at the maximum expanse.⁴⁰ Generally, at these sites there are variants that look like local products adapted to “interregional” fashion, rather than western vessels that are either imported or locally made.

Figure 17 shows a group of globular or sub-globular

jars and similar types. Figure 17.1–8 illustrates one of the most common forms found in the Mahtoutabad III deposits, a plain globular pot with a short, round everted rim. The distribution of the mouth diameter values, in spite of the limited number of measurements, suggests an assemblage of medium-sized pots or jars in two size clusters, one around 15–19 cm, the other wavering between 21 and 24 cm. Many of these pots have a pattern of multiple parallel grooves running on the shoulder, combed when the clay was plastic, and a vertical flat or strap handle joining the rim to the base of the shoulder (see Fig. 17.3). Standard versions of this type are very common at sites in Susiana,⁴¹ and other secondary attributes such as the horizontal twisted handle (Fig. 17.5)⁴² or the cross-hatched incised patterns (Fig. 17.7)⁴³ stress a strong connection with the west.

⁴¹ Delougaz and Kantor 1996: pls. 95, F–N; 96; some variants in pls. 97–98; for Tepe Farukhabad, see Wright 1981: fig. 50, a and 55, j.

⁴² Delougaz and Kantor 1996: pl. 101, A–G, I, J; vertical twisted handles appear on the same vessels in pl. 100; the same variant at Tepe Farukhabad, in Wright 1981: fig. 55, k, l.

⁴³ Delougaz and Kantor 1996: pls. 97, D; 98, J, K, I; 100, F; 101, E.

These vessels, which appear to be so important at Chogha Mish and Mahtoutabad, are completely absent at Tepe Yahya and Tal-e Malyan. At Arisman, simple globular pots of the same general form are common, and the handle is applied in the same position,⁴⁴ but its section, as a rule, is round rather than flat and the shoulder is always plain. At Godin Tepe, single-handled globular pots, called “beer jars”,⁴⁵ might represent the same type and functions, but they bear notched ridges in relief instead of incised lines, and the thick handles resemble those of the Arisman handled pots. The forms of Godin Tepe and Arisman look like a local re-elaboration of an interregional model.

Figure 17.9–15 shows elements of globular pots and/or jars, which cannot be commented on in greater detail. Figure 17.16–17 are small biconical jars, a rather uncommon form in the inventories so far reviewed, with the possible exception of the pitchers with rim spouts.⁴⁶ The small hole-mouth jar shown in Figure 17.18 is very similar to a vessel found at Aris-

⁴⁴ Helwing 2011a: 229, 230, figs. 17 and 18.237; fig. 25.110, 111, 114, 115 and 118–120.

man.⁴⁷ Its lower body was extensively trimmed with vertical movements.

Coarse, heavily chaff-tempered oval trays with a low side (Fig. 18.1–2 and Fig. 19) are another recurrent type of this chronological and cultural horizon. The trays at Mahtoutabad have a short sub-vertical and inward-inflected wall ending in a rounded rim. There are also trays with outward-inflected walls, which in general are higher than the former ones. The second form was in use at Chogha Mish, but is better documented at Tepe Farukhabad, Tepe Yahya and Tal-e Malyan,⁴⁸ as well as at Tol-e Spid.⁴⁹ Both types, however, were used at Chogha Mish, Tal-e Malyan, Godin Tepe, Tal-i Iblis, Tepe Sofalin and Arisman.⁵⁰ At Arisman a drop-shaped tray, evidently conceived for pouring from the restricted side,⁵¹ has the same technical implications of the spouted rim of the Mahtoutabad

Coarse chaff-tempered ware, pale brown (10 YR 6/3), coated inside and on the exterior surface with a film of heavily chaff-tempered clay. Mouth diam. 12 cm. 22. Lot 19/167. Coarse, sand-tempered ware, reddish yellow (7.5 YR 6/6). The inner bottom is covered with a grit-like surface. Base diam. 21 cm. (Image M. Vidale and F. Desset.)

Fig. 19. Mahtoutabad: fragments of low-sided coarse chaff-tempered trays. (Image M. Vidale.)

one, while an oval tray found at Tal-e Malyan⁵² is almost identical to our specimens.

These trays are generally broken into small fragments and determining the original diameters is often difficult. Due to the inward-inflexed rim, measures are better taken on the base than on the rim. The variations of the mouth diameter of oval trays (from excavated area and surface lots) appear in Table 4.

The two clusters (respectively *c.* 26–27 and 32–35 cm) are due to the oval shape of the vessels, suggesting an average length of *c.* 38/40 × 28 cm. The measurements, however, also show the presence of a certain number of specimens of much larger size.

The low-sided rectangular tray or box shown in Figure 18.3 is very coarse and in spite of its superficial resemblance to some of the crucibles from Tal-i Iblis,⁵³ may have been a small mould for a flat copper object. Similar objects were also found at Arisman and on the surface of Banesh sites in the Kur River Basin.⁵⁴

While the fragments shown in Figure 18.6–8 demonstrate that our assemblage includes thin-walled hemispherical bowls of variable size, the finely fashioned bowls in Figure 18.4–5 and 9–11 are another recurrent type. They were made with a fine clay in a relatively standardised size, around 20–22 cm. The body is hemispherical, with a slightly S-shaped overall contour, and the lower inflection point being the limit of the lower turned area. The projecting rim has a distinctive upper flat tangency, and sometimes rows of short lines and dots, incised or painted. Such bowls were probably made on the potter's wheel using a coil-building process.

Variants of the same type were found at Tol-e Nurabad,⁵⁵ Tol-e Spid,⁵⁶ Chogha Mish,⁵⁷ Arisman Area C ("Proto-Elamite")⁵⁸ and Tal-i Iblis.⁵⁹ Although the type is obviously the same, in each region the model was re-interpreted and recreated. The Mahtoutabad III

specimens are fine products, and are better compared with similar vessels at Arisman Area B,⁶⁰ linked by the means of ceramic comparisons to Sialk III (*c.* 3500 BC), rather than with Arisman C contexts. The possibility that some materials in the Mahtoutabad III assemblage correspond to these horizons is enhanced by the comparanda for Figure 18.14—an open bowl with a slightly S-shaped profile, weak carination and pointed rim—with Figure 18.15 as a possible painted variant.⁶¹ Together with this type, the small bowls with a club-like rim (Fig. 11.12–13) and the miniature truncated-cone-shaped bowls (Fig. 18.16–19) are also very similar to specimens from Arisman area B.⁶² The thick-walled conical bowl (Fig. 18.21) is coated with a thin layer of chaff-tempered slip, both inside and outside; it is a *unicum* and might have been used in a specific yet unknown activity.

III.2. "Local" painted pottery types

Painted light buff wares (Fig. 18.15 and Figs 20, 21, 22 and 23) amount to no more than 2–3% of the total, and may be local and/or regional types. Their inventory includes some types not represented in our figures, such as fragments of large globular jars painted with broad black and red horizontal bands, truncated-cone-shaped bowls with wide intersecting festoons hanging from the inner rim, and a small pot or jar with bichrome (black and red) geometric patterns. The bulk of the painted wares at Mahtoutabad III, however, are fine, small restricted jars or carinated pots bearing simple dark grey painted geometric friezes (Fig. 21.2–10). Bases of small- and medium-sized buff ware jars (Fig. 21.12–17) might belong to the same class of containers.

The local painted types (Fig. 24) match pots found in other sites, such as Tal-i Iblis, and might well be part of the same regional tradition. While the technical quality of these small- to medium-sized vessels is often excellent, particularly for the smaller bowls (fine paste, thin walls clinky to the touch, smooth surface, uniform firing conditions), the designs are limited to

TABLE 5. Classification and statistics of Mahtoutabad III ceramics in lot nos. 16–21 (materials found in the fillings of two looting pits, later included in Trench V).

Type or item	Description/part of vessel	Quantity	%
low-sided tray	rim fragments	25	2.47
low-sided tray	base fragments	16	1.58
bevel-rim bowl	rim fragments	47	4.64
bevel-rim bowl	wall fragments	29	2.89
bevel-rim bowl	base fragments	64	6.35
truncated-cone bowl	rim + wall fragments	22	2.17
bowl with pointed rim	rim fragments	19	1.87
flowerpot	base fragments	14	1.38
flowerpot	wall fragments	12	1.18
vase with round bottom	bases	4	0.39
vase with round bottom	wall fragments	25	2.49
vase with rim spout	rim fragment + spout	5	0.49
shoulder spout	wall fragments + spout	12	1.18
globular jar, grooved	(rim, shoulder, handle)	25	2.47
medium-large jar	rim + shoulder	21	2.07
medium-large jar	plain wall fragments	211	20.89
medium-large jar	base fragments	7	0.69
medium-large jar	wall fragments, painted	15	1.48
nose-lug jar	shoulder fragment	1	0.09
carinated jar	shoulder fragments	4	0.39
small jar, flat rim	rim fragments	15	1.48
small jar	shoulder fragments	6	0.59
small jar or bowl	wall fragments	358	35.43
small jar or bowl	flat base fragments	27	2.67
small carinated jar	rim or shoulder fragments	9	0.89
miniature vessel	(unpainted) fragments	3	0.29
small jar or bowl, painted*	various fragments	15	1.48
Total		1011	100%

* black on light cream to white, black on buff, black and red on buff

friezes of double zigzag lines, wavy lines and festoons, hatched triangles, hatched bands and butterfly/hourglass patterns.

III.3. A quantitative estimate

Table 5 presents the counts of the sherds collected inside two illegally dug pits where the Mahtoutabad III layer was particularly thick and rich in material. These counts are complicated because some types (like BRBs) are immediately recognisable even from small sherds, while others can be identified only through the presence of smaller and less common distinctive elements (e.g. spouts and lugs). Similarly, small base fragments of oval trays can hardly be distinguished

from those of other pots, and fine small jars cannot easily be identified from bowls of the same size. The sturdy cylindrical base fragments of flowerpots are very easy to identify, but their thin walls and tiny rim fragments are not, and were probably counted in other groups. Thus, the values of Table 5 are indicative, rather than absolute.

A total number of 1011 sherds were counted in this sample. This selected sample is dominated by restricted vessels, mainly scarcely diagnostic sherds of small-sized containers (small jars and bowls) amounting to 35.43% of the total, followed by plain fragments of medium-sized jars (20.89%). More than half of the vessels in this sample, therefore, might have been dedicated to the storage and movement of solids and/or liquids, especially considering the very limited

evidence of soot marks that one would have expected if cooking pots were on record. The Mahtoutabad III pottery clearly did not come from a cooking facility. BRBs (rim, wall and base fragments, total $n = 140$) account for 13.84% of the total (approximately the same percentage was independently confirmed by counting the material collected on the surface and in other lots from the Trench V excavation). Oval low-sided trays ($n = 41$) represent 4.05% of the total. Flowerpots (total $n = 26$) form 2.56% of the sample, but this value is most probably underestimated (see above). Painted potsherds ($n = 30$), including both large jars and small finer vessels, represent, as stated above, no more than 2.96% of the sample. Very large storage jars seem to be absent. It is impossible to say if this reflects the original ceramic assemblage and its functions or if it is a side effect of the local deposition processes.

III.4. Manufacturing technology

With the obvious exception of BRBs and a few other types, the Mahtoutabad III pottery was fashioned on the potter's wheel, sometimes after a coil-building process. Various medium- or large-sized restricted vessels were made by combining forms of coil building and wheel fashioning.

BRBs were obviously moulded in some kind of container or cavity. The incorrect idea that these vessels were hand-formed by free manipulation (but how exactly?)⁶³ developed from the observation of fingerprints on the exterior, which were actually left when potters extracted these vessels, still in plastic state, from the mould. One or more thick slabs of chaff-tempered clay, sometimes with seed imprints, were pressed in the bottom of the mould—leaving deep finger or knuckle marks in the inner base—and then lifted up to about one third of the vase's body.⁶⁴ Several other slabs were then carelessly applied on top of the initial slabs to build the wall. The last slabs, which were applied to shape the rim, were generally

thicker than those of the mid-body. As potters pressed the clay insistently at the edge of the inner base, the centre was often much thicker than the inner edge of the base. The interior was smoothed with water or slip, sometimes alternating vertical pull movements and oblique ones (as in Fig. 10.8). When the vessel, still in partially plastic conditions, was detached from its mould and lifted with a rapid rotating movement, the mid-wall, thinner than the rest, often retained a spiral-like twist.⁶⁵ Under the outer rim there are often deep, rhythmic finger impressions, possibly left while forming the rim, but also during the detachment. The uneven thickness caused frequent cracks during drying, particularly within the base. The residual plasticity of BRBs at the moment of their extraction suggests that they were quickly made in large lots and extracted after a short interval—potentially within one hour. The firing conditions are in general even, as a rule in slightly oxidising atmospheres, and do not produce blackish spots on the vessel surface.

The Mahtoutabad flowerpots are strange vessels—very thick and sturdy at the base, and extremely fragile at the slightly thickened rim, to the point that it is hard to imagine that they had a long life. As a rule, they seem to have been fashioned from a single lump centred on the potter's wheel, but one large specimen was first made by moulding its base as a finished BRB.⁶⁶ This ostensible BRB was extracted from its mould and placed, before drying, on the potter's wheel and raised through the addition of a series of superimposed large coils on the base. The now tall vessel was then finally shaped on the fast-revolving wheel (a particularly clear example of “hybrid” technology).

It was once thought that BRBs were products of a somehow brutal, non-skilled serial labour, but this, on the contrary, suggests that their making was simply a part of a still complex technical know-how of the potting communities of the time. In the same workshop areas, potters shifted from slab moulding to wheel throwing, even within the same production cycles. Another example of this complexity is the long bottles with downward-bent spouts and truncated-conical turned bases of Susiana, which were doubtless made by coil-building and shaping on the potter's wheel and built in superimposed sections; but perhaps we should

⁶³ Rothman and Badler 2011: 89.

⁶⁴ H. Wright (1981: 128) proposed that BRBs at Tepe Farukhabad were made with a single clay lump quickly pressed in a mould/ground cavity, but at Mahtoutabad the thickness reduction in the mid-wall and its frequent twisting when the vessel was lifted rather suggest a slab construction process. For a summary of the various ideas on the construction of BRBs (and their function), see Goulder 2010.

⁶⁵ The same defect is clearly recognised in some BRBs from Godin Tepe (e.g. Badler 2002: fig. 13, B1 479 no. 1 and B1 479 no. 5).

⁶⁶ As described in Vidale 2011.

not assume that the Mahtoutabad examples were made locally.

Oval trays were made with the same chaff-tempered material, but were entirely hand-fashioned with slabs in the base, and with one or two coils for the wall and rim. The bottom often retains deep finger tracks. The use of large and flat moulds for the bases is possible but hard to demonstrate.

The finer small-sized vessels were entirely fashioned on the potter's wheel, and their bases were later thinned by placing them upside down on the same device and thinning them by turning the bases with a blade, before the vessels were completely dry. The finer small painted bowls were frequently polished to a variable extent before painting and firing.

With the exception of the BRBs and low-sided trays, the Mahtoutabad III pottery shares medium and often quite fine fabrics with scarcely visible inclusions, and firing was distinguished by medium-high temperatures reached in slightly reducing atmospheres, often resulting in shadows from white or light buff to pale yellow or even light green. The ware was typically compact and clinky. The general impression is of a competent, rather standardised mass production; potters mastered a combination of hand forming, moulding, coiling and wheel-throwing techniques, with little aesthetic concern but with highly controlled firing processes.

IV. OTHER FINDS

A limited number and range of other finds were recovered. Animal figurines (Fig. 25.1–2) include a small, well-fired terracotta specimen that might have portrayed a fat-tailed sheep, and the head of a larger terracotta bull, the original of which must have been about 15 cm long or more. The bull was modelled in massive form and was painted with dark stripes, while the front bears multiple impressed dots.

The small finds assemblage also contained three median fragments of terracotta sickles (one reconstructed in Fig. 25.3–5). These artefacts are typical of Ubaid Mesopotamia, but are rather uncommon in the fourth-millennium BC contexts discussed so far (i.e. they have never been found at Tal-e Malyan, Arisman or Tepe Yahya). They have a distinctive drop-shaped section, one of the surfaces was covered with sand (possibly for an easier detachment from the kiln's

Fig. 25. *Terracotta figurines and sickles.* 1. *Terracotta animal (sheep ?) figurine fragment, length c. 6 cm.* 2. *Terracotta bull (?) figurine fragment, length c. 15 cm.* 3. *Terracotta sickle fragment.* 4. *Terracotta sickle fragment.* 5. *Terracotta sickle fragment.* (Image M. Vidale, F. Desset and R. Micheli.)

surface) and they appear to have been fired at high temperatures.

Figure 26 shows a collection of jar stoppers or lids in unbaked clay (1–8) and two seal impressions in the same material (9 and 10). All of these objects were found clustered in a restricted spot of Trench V—a primary dump of sealings and some complete BRBs—in front of the alluvial deposits (see Fig. 5).

The lids (Fig. 26.1–4) are small clay disks, sometimes retaining the edge and a convex profile, which might have been used to close and re-open small- to medium-sized restricted containers. Very similar objects of the same size were found in large numbers at Chogha Mish⁶⁷ and were also used at Godin Tepe and Tal-e Malyan.⁶⁸ Their diameters seem to have ranged between 5 and 10 cm. While no closure of this general type could be ascribed to the mouth of a BRB, Figure 26.5 retains the possible imprint of a basket, and Figure 26.6–8 had been clearly applied on the neck of restricted jars (Fig. 26.6 also retains a cloth impression on the interior).⁶⁹ Objects bearing seal impressions (Fig. 26.9–10) are fragments of flat clay sheets that might have been applied to wooden boxes or similar packages. Figure 26.9, which was probably produced by the use of a cylinder seal, shows a long-horned goat framed by vertical lines. Figure 26.10, which was also impressed with a cylinder seal but is poorly preserved, retains some fine scrolls, and the edge of the impression is marked by one or two lines of dots in relief.

Two fragments of perforated weights in travertine are illustrated in Figure 27. Both were found in the same layer, together with pieces of BRBs, flowerpots and other vessel forms. The original shape of the weights was hypothetically reconstructed by combining the formal information of both finds (Fig. 27.3 and design at the bottom).

V. DISCUSSION

East of the plains of Mesopotamia, ceramics generically qualified as “Uruk-related”⁷⁰ have been recovered in several regions and sites (Fig. 1).⁷¹ These include: Susa (periods II and III);⁷² Chogha Mish (proto-

literate period)⁷³ and Tepe Sharafabad in Susiana;⁷⁴ Tal-i Ghazir⁷⁵ on the Ram Hormouz plain; Tepe Farukhabad⁷⁶ on the Deh Luran plain; Kamtarlan;⁷⁷ Chogha Gavaneh; Godin Tepe⁷⁸ and three other sites⁷⁹ in the valley of Kangavar; 11 sites with BRB sherds on the surface⁸⁰ in Kermanshah/Mahidasht, Chia Fatela and Chesmeh Sardeh near Tepe Guran in Hulailan; Tepe Giyan⁸¹ and Baba Jan V⁸² in Nehavand; three sites with Uruk-related materials⁸³ in Khorramabad, Tepe Ghabrestan (period IV, levels 3–1)⁸⁴ and Tepe Ozbaki/Tepe Marra⁸⁵ in the Tehran⁸⁶ and Qazvin plains; Tepe Sofalin⁸⁷ in the Pishva-Varamin plain; Qoli Darvish;⁸⁸ Tepe Sialk (period IV)⁸⁹ and Arisman⁹⁰ on the Central Plateau; Tol-e Nurabad and Tol-e Spid in the Mamasani region;⁹¹ Tal-e Malyan (middle and late Banesh)⁹² and Tal-i Kureh (initial/early Banesh)⁹³ in the Kur River Basin; Tepe Yahya (phase

IVC);⁹⁴ Tal-i Iblis (periods IV–VI)⁹⁵ and Mahtoutabad (period III) in Kerman; and a small number of BRBs have also been found in Kech-Makran, at Miri Qalat (period IIIa; end of the fourth/ beginning of the third millennium BC).⁹⁶ So far no Uruk-related pottery type was reported in the plains of Damghan and Gorgan, in Khorasan or in the Kopet Dagh piedmont, in the Hilmand basin or in the basin of the Urmia Lake.⁹⁷

A general review of the detailed absolute dates of the mentioned sites is beyond the scope of this article. Nonetheless, it is clear that from *c.* 3500 BC or possibly even earlier (as suggested, for example, by the determinations from Tepe Sharafabad, Tol-e Spid and Tol-e Nurabad; see Petrie *in press*), several ceramic types generally associated to the contemporary ceramics produced in lowland Mesopotamia (in the first place the BRBs) appeared, often *en masse*, on the Iranian plateau.

In sites like Tol-e Spid, Tol-e Nurabad and Tal-e Kureh, where the distinction between the late Lapui and initial Banesh phases is not straightforward, at Tal-i Iblis where Period IV is poorly defined or at Tepe Sialk where Uruk-related material was actually found in late Period III_{6–7}, these vessels forms appear without any clear break with the previous traditions. In contrast, the Mahtoutabad III secondary layers came from a site apparently isolated from previous or later occupations. The clay sealings, the pottery forms recorded and the broken travertine weights qualify the area as a dump after the completion of a variety of small-scale controlled transactions involving different types of containers (small jars, possibly baskets and wooden boxes). Containers were frequently opened and closed, while large numbers of BRBs circulated and were discarded on the spot. With the exception of the possible rectangular copper moulds discussed above, we found no material evidence of specific craft activities, and the apparent absence of large-sized jars (see above) might play against the hypothesis of an important long-term storage facility.

While the Uruk-related ceramic complexes found in Iran have often been described as being indicative of a single, pervasive interaction sphere centred in the west, the new Mahtoutabad III assemblage reveals a complex and intriguing pattern of interference, particularly through evidence of links but also important gaps with the other involved sites. In the first place, the formal identity of some types of carinated four-lugged jars, terracotta sickles and tall jars with bent spouts suggests a preferential, possibly non-mediated link between the Halil Rud valley and the Susiana and/or Mesopotamian centres. Terracotta sickles, which derive from an ancient Mesopotamian tradition of the fifth millennium BC, are intriguing, because on the Iranian plateau the abundance of silicastic rocks needed for blade manufacturing would rule out the techno-economical need of making ceramic sickles. Widely used across the Susiana plains in the fourth millennium BC, particularly in the early and middle Uruk period,⁹⁸ ceramic sickles might have been required in the Halil Rud valley for a specific technical process, beyond harvesting cereals. Nonetheless, while many have hypothesised that the reason for the “Uruk phenomenon” was intercepting local flows of raw materials at the highland sources,⁹⁹ terracotta sickles would rather show an opposite attitude, that is carefully avoiding local materials and technologies in favour of a technique doubtlessly rooted in alluvial geomorphological contexts with limited access to flint, chert and similar rocks.

At Arisman and Tepe Yahya, four-lugged jars were replicated in terms of local, regional traditions, while at Godin Tepe four-lugged jars with incised decoration identical to the western models and local painted variants were both encountered. Similarly, the strap-handled pots with grooved shoulder common at Mahtoutabad III point to a straight connection with the west, whereas the “contemporary” communities at Godin Tepe and Arisman seem to have recreated their own versions of the same model. Some types point to links in other directions. Flowerpots, for example, might link Mahtoutabad with several Mesopotamian sites, but not to the wide repertory of Chogha Mish. Mahtoutabad shares this tall vessel with Tal-e Malyan and Tepe Sialk, but apparently to the exclusion of other sites like Tepe Yahya and Arisman. Besides

BRBs, low-sided trays are probably the most ubiquitous type, but in both cases more detailed typological studies might reveal variations in form, function and chronology that are at present still implicit.

VI. CONCLUSIONS

As with all of the sites discussed here, the fragmentary picture that has been observed might be an artefact of the relative size of the excavated areas, location, activity patterns and stratigraphic formation processes at the various excavated sites. Each assemblage, furthermore, might be the casual contingency of a specific historical event, deformed by the partiality of the preserved and excavated lots. Even the shape and tectonics of each pottery type, as discussed above, which in turn depends on manufacturing technology, may dramatically affect our counts and reconstructions. All this becomes even more slippery when the still scarce chronological definition of the involved horizons is considered, as we are dealing with a time range of several centuries, for which absolute dates show a wide range of fluctuation.¹⁰⁰

Two crucial questions, however, cannot be eluded: exactly how old is the pottery of Mahtoutabad III (if it actually is a synchronous assemblage)? And what is the historical explanation, or the economical *raison d'être* of the community that used these peculiar ceramics at the piedmont of the first mountain ranges of Baluchistan?

The chronology of the Mahtoutabad III assemblage is a difficult issue. In the absence of absolute dates, we can only compare our ceramics and related dates with those from other excavated sites. As we have seen, both the pottery sickles found in Trench V and the probable links with Susa Acropole I.17 and the Early Banesh in Kur River Basin would point to a mid-fourth-millennium BC date, which is supported by further positive comparisons with Arisman Area B outlined above, which is in turn linked with Sialk III₆₋₇.

The validity of pottery links can be questionable, because the formal comparison of graphic illustrations has an inescapable component of subjectivity, and stratigraphy is recorded at variable levels of analytical confidence. Nevertheless, we appear to have traced very early evidence of the use of several Uruk-related ceramic types at a surprising distance from southern

¹⁰⁰ Petrie in press.

Iraq, close to the still mysterious frontier with the early Indus world. The Halil Rud floodplains seem somehow to have been linked to Khuzistan at the beginning of the urban explosion of Uruk and Susa, but the form and rationale for this linkage is at present unclear.

In the past, the “Uruk phenomenon” outside Mesopotamia has been discussed at length.¹⁰¹ In a minimalistic view, similarities in pottery are seen as simply being due to cultural influence from Mesopotamia,¹⁰² while more demanding theories suggest that pottery and its models were transported from Mesopotamia eastwards and northwards by human groups shifting on the wake of variable interests.¹⁰³ For the Iranian plateau the most relevant explanations have been reviewed by Petrie (2013a), highlighting the arguments about communication, shared cultural milieus, strategic control of interregional trade, elite emulation, migration and colonisation, and more recent trade-diaspora models, which are distinguished by reciprocal or mutually exploitative relationships, to account for decreasing levels of political control and lesser cultural uniformity with increasing distances.

In most of these models, the asymmetric distribution of natural resources (in the first place of copper, lead and silver ores) between lowlands and highlands plays a major explanatory role. But how does the Mahtoutabad III evidence fit in with such a theoretic-

cal framework? Archaeological evidence at the Konar Sandal site complex shows intensive exploitation of copper ores in a specialised craft neighbourhood during the second half of the third millennium BC,¹⁰⁴ and other important metallurgical settlements are known in the Halil Rud valley in the later historical periods (surveys by N. Alidadi Soleimani). That the Halil Rud communities of the mid-fourth millennium BC were similarly involved in the procurement and transformation of local copper and lead/silver ores—as at Tepe Sialk and Arisman¹⁰⁵—is quite likely, but our only witnesses to this are two fragments of rectangular moulds for casting copper (Fig. 18.3). On the other hand, a limited test trench in the much-disturbed Mahtoutabad I occupation layers showed that local societies were actively involved in the production of alabaster vessels and in copper processing already in the late fifth–early fourth millennium BC,¹⁰⁶ well before the Uruk phenomenon. In this (very partial) light, the interference of the communities using the Uruk-related vessels seems to be a consequence, and not a causative factor, of local processes of socio-economical evolution. Moreover, the striking similarity of the ceramics we described to the Khuzistan assemblages, at a site more than 1000 km east of Susa, does not fit easily with models envisaging decreasing cultural interaction with increasing geographical distance, and poses challenging new questions in our efforts at archaeological interpretation.

Ultimately, the meaning that we should attribute to the appearance of these wares across the Iranian plateau, and the significance that should be given to the material links with Mesopotamia—where such ceramics *might* have been previously produced¹⁰⁷—most probably cannot be properly discussed on the basis of the relatively

¹⁰¹ e.g. Edens 2002: 40; Butterlin 2003: 139–151; Potts D.T. 2009: 7–14.

¹⁰² For Forest (2000: 142) the diffusion of BRBs could simply be the result of the diffusion of a peculiar ceramic manufacturing technique.

¹⁰³ Amiet (1986: 49) has argued that this involves the migration of small groups of craft specialists. D.T. Potts (1999: 65–67) has hypothesised a limited migration from Mesopotamia to Susiana, without attempts at politically controlling the region. In contrast G. Algaze (1989, 1993, 2001, followed by Potts T.F. 1994: 78) thinks that Susiana was conquered by Mesopotamian polities of the Uruk period, establishing a linked series of outposts as trade enclaves for controlling the exploitation of local resources. For Englund (2006: 7) the procurement of such goods took place in “politically undeveloped mountainous regions, not encumbered by ownership claims”. Kohl (2007: 222–23) proposed a growing interest for new breeds of sheep and goats and better qualities of wool available from the Caucasus to the plateau, while for Lamberg-Karlovsky (2008) masses of farmers abandoned Sumer in search of better and free agricultural estates in foreign lands. No one, however, discusses the functions of the Uruk-related ceramic types in relation to the activities and socio-economic processes hypothesised to explain the expansion.

¹⁰⁴ Madjidzadeh and Pittman 2008: 86 (trench IX).

¹⁰⁵ See Helwing 2013.

¹⁰⁶ Vidale and Desset 2013.

¹⁰⁷ See Wright and Rupley 2001 for the dating of the “Uruk-related assemblages” in southern Iraq. The anteriority of these material complexes west of the Iranian plateau is not supported by the data. The oldest assemblages of this type, and in particular of BRBs (markers of the middle Uruk phase) come from the sites of Abu Salabikh and Tell Qraya. Dates of Abu Salabikh range from c. 3950–3660 BC to 3650–3380 BC; while at Tell Qraya c. 3900–3370 BC, 3940–3380 BC and 3950–3380 BC (all calibrated, 95% probability). The radiocarbon datings of Tepe Sharafabad, Tol-e Spid and Tol-e Nurabad are contemporaneous with those of Abu Salabikh and Tell Qraya.

threadbare evidence that is presently available.¹⁰⁸ We should, however, continue to deconstruct previous concepts and get back to the hard core of the material evidence, as this will force many traditional models to be thoroughly revised. For example, reference to the intercepting of raw materials should be supported by evidence of storage facilities for the same goods, or to the factual record of local large-scale transformation activities (e.g. indicators of textile processing or of copper-smelting processes), and not to proximity to trade routes and potential geopolitical entities. Also, Uruk-related ceramic types should be interpreted in terms of their function, social role and gender ascription, rather than their formal description.

The daily material aspects of a society (which may be found in excavations, such as ceramic production, glyptic, architecture or writing) are not necessarily intertwined in a monothetic structure. They may well have evolved independently, with various speeds and adapted differently, in contexts whose contemporaneity is still beyond our present power of archaeological assessment.

While the “Uruk-related” ceramic types appeared in various regions of the Iranian plateau around 3500 BC (or even before), there are in Iran no architectural structures comparable to what is observed in Greater Mesopotamia, as would be the case in a true colonisation.¹⁰⁹ In the second half of the fourth millennium BC the site of Godin Tepe, frequently quoted as an example of supporting evidence for an “Uruk expansion”, shows rather surprising and important architectural similarities with buildings excavated in Tal-e Malyan and Susa (F. Desset, ongoing research). At the same time, however, Godin Tepe and Tal-e Malyan are likely to be slightly different in date and used different systems of graphic recording: the former had numeral and numero-ideographic writing, the latter Proto-Elamite writing. In short, we face a very complex, multi-faceted and badly preserved archaeological reality, and given the very poor control we still have of the absolute chronology, to accept our ignorance in principle seems more useful than embracing grander, more adventurous reconstructions.

¹⁰⁸ See the criticism of Pollock (2010: 107) concerning the “sterile debates about the meanings of archaeological entities”.

¹⁰⁹ In contrast, at Habuba Kabira and Djebel Aruda in Syria, populations shared all the material aspects of the southern Mesopotamian way of living (primarily, architecture); in these contexts, many would agree that the use of the term “colony” is not excessive.

The evolution of the material culture of fourth-millennium BC Middle Asia should be considered in terms of an unparalleled but still largely unknown process of discontinuous *interregional standardisation* that affected in different phases and to different scales ceramics, glyptic, architecture and writing. The ceramics of Mahtoutabad III, with their intriguing framework of formal identity, similarities, differences and relationships of presence and absence with important pottery types with other sites and across distant regions, are a new fragment of this developing picture.
