Abstract

We propose a new typed graphical language for quantum computation, based on compact categories with biproducts. Our language generalizes existing approaches such as ZX-calculus and quantum circuits, while offering a natural framework to support quantum control: it natively supports “quantum tests”.

The language comes equipped with a denotational semantics based on linear applications, and an equational theory. Through the use of normal forms for the diagrams, we prove the language to be universal, and the equational theory to be complete with respect to the semantics.

Keywords and phrases Quantum Computation, Linear Logic, Graphical Languages, Geometry of Interaction

1 Introduction

Conventional wisdom has it that quantum computation is about quantum data in superposition. In the standard model, the memory holding quantum data is encapsulated inside a coprocessor accessed through a simple interface: The coprocessor holds individually addressable registers holding quantum bits, on which one can apply a fixed set of operations — gates — specified by the interface. If some of these gates can generate superposition of data, this is kept inside the coprocessor and opaque to the programmer. A typical interaction with the coprocessor is a purely classical sequence of elementary operations of the form “Apply gate X to register n; apply gate Y to register m; etc”. Such a sequence of instructions is usually represented as a quantum circuit. In this model, a quantum program is then a conventional program building a quantum circuit and sending it as a batch-job to the coprocessor.

From a semantical perspective, the state of a quantum memory consisting of n quantum bits is a vector in a $2^n$-dimensional Hilbert space. A quantum circuit is a linear, sequential description of elementary operations describing a linear, unitary map on the state space. The quantum coprocessor should come with a universal set of such operations, that is, such that any unitary operation on the state space can be realized using the given elementary gates.

If unitary maps form the original representation for (pure) quantum operations, this extensional presentation makes a very rough semantics for the interaction with the quantum memory. It is akin to say that one could abstract a conventional program by the plot of
the corresponding function: this hides useful information one might want to keep track of, such as topological constraints, composition of subroutines and execution flow, required resources or other costs, etc [33]. Most of the structure of the computation is lost in the matrix representation.

Coming all the way from Feynman’s diagrams [22], graphical languages for representing quantum processes can be seen as an answer to the limitations of plain unitary matrices. In recent years, in the field of quantum computation has blossomed a wide variety of proposals to focus on specific aspects of the semantics of quantum programs [23, 14, 8].

Quantum circuits are an obvious candidate for a graphical language, and indeed, several lines of research took them as their main object of study [24, 16, 30, 7]. Quantum circuits in particular form a natural medium for describing the execution flow of a computation. Similar to the intuition one can build for classical boolean circuits, one can make an operational semantics for quantum circuits using a token-machine Geometry of Interaction. Each token in the circuit carries a quantum bit, and they flow in the circuit from inputs to outputs while getting modified as they pass through gates [16]. The main problem with the model of quantum circuits is the lack of a satisfactory equational presentation. If several attempts have been made for various subsets [12, 11, 26, 27], none of them provides a complete presentation.

A recent proposal answering the defects of quantum circuits as a (formal) language is the ZX-calculus [14]. Rooted in category theory [1], it comes with a small set of generators and a sound and complete equational theory [36]. Conservative extension of quantum circuits, yet versatile, the ZX-calculus has shown its use in a wide variety of applications, ranging from optimization [20, 3], verification [21, 19], and error-correction [17].

Despite its success, the ZX-calculus is nonetheless still tied to the quantum coprocessor model. Indeed, it fails to account for one peculiar feature of quantum computation: non-causal execution paths. Indeed, the Janus-faced quantum computational paradigm features two seemingly distinct notions of control structure. On the one hand, a quantum program follows classical control: it is hosted on the conventional computer governing the coprocessor, and can therefore only enjoy loops, tests and other regular causally ordered sequences of operations. On the other hand, the lab bench turns out to be more flexible than the rigid coprocessor model, permitting more elaborate purely quantum computational constructs than what quantum circuits or ZX-calculus allow.

The archetypal example of an quantum computational behavior hardly attainable within ZX-calculus (or quantum circuits) is the Quantum Switch. Consider two quantum bits $x$ and $y$ and two unitary operations $U$ and $V$ acting on $y$. The problem consists in generating the operation that performs $UV$ on $y$ if $x$ is in state $|0\rangle$ and $VU$ if it is in state $|1\rangle$. As $x$ can be in superposition, in general the operation is then sending $(\alpha |0\rangle + \beta |1\rangle) \otimes |y\rangle$ to $\alpha |0\rangle \otimes (UV |y\rangle)_x + \beta |1\rangle \otimes (VU |y\rangle)$. It is a purely quantum test: not only can we have values in superpositions (here, $x$) but also execution orders. This is in sharp contrast with what happens within the standard quantum coprocessor model.

Computational models supporting superpositions of execution orders have been studied in the literature. One trend of research consists in proposing a suitable extension of quantum circuits [9, 31, 35, 37]. These approaches typically aim at discussing the notion of quantum channel from a quantum information theoretical standpoint. Another research line is concerned with exhibiting the execution flow internal to ZX-terms in a distributed manner [6]. Somewhat similarly to what has been proposed in [16], tokens are let to flow in a ZX-term, realizing the computation, the difference being that the tokens can themselves be in superposition. The limit is however that a ZX-term is inherently causal, therefore restricting the possibilities for superposition of orders.
One limitation of the existing extensions of quantum circuits or of graphical languages based on ZX-calculus is the limited support for typed quantum data. In the context of quantum circuits, the strategy has been to consider extended structures stemming from proof-nets and resource-sensitive logics such as linear logic. A proof-net is a structured graph describing a proof of a linear logic formula. Through the Curry-Howard isomorphism, a proof can be regarded as a program and a formula as a type specifying how the program handles resources. This turns out to be particularly well-suited for quantum computation [18, 29, 16].

In the approaches merging quantum circuits with types based on linear logic, the additive types such as the sum-type are purely classical: \(1 \oplus 1\) is always a (conventional) boolean. In quantum computation, the sum-type \(1 \oplus 1\) can however be understood as a sum of vector spaces, giving an alternative interpretation to \(1 \oplus 1\): it can be regarded as the type of a quantum bit, superposition of True and False. One should note that this appealing standpoint should be taken cautiously: (Pure) quantum information imposes strong constraints on the structure of the data in superposition: orthogonality and unit-norm have to be preserved [2, 32].

The standard categorical formalization underlying quantum computation, whether with the coprocessor or with the purely quantum viewpoint, is symmetric monoidal categories, and compact closed categories in particular. The monoidal structure stands for the tensor of quantum data, while coproducts are used to represent “tests”, whether classical [16, 18] or quantum [32].

Graphical languages for symmetric monoidal structure with coproducts usually rely on a notion of sheet, or worlds, to handle tests and coproducts in general [18, 28]. Figure 1a shows for instance how to represent the construction of the morphism \(f \oplus g : A \oplus A' \to B \oplus B'\) out of \(f : A \to B\) and \(g : A' \to B'\). The symbol “\(\oplus\)” stands for the “split” of worlds. Such a graphical language therefore comes with two distinct “splits”: one for the monoidal structure —leaving inside one specific world—, and one for the coproduct —splitting worlds—. They can be intertwined, as shown in Figure 1b. Another approach followed by [15] externalizes the two products (tensor product and coproduct) into the structure of the diagrams themselves, at the price of a less intuitive tensor product and a form of synchronization constraint.

However, in the state of the art this “splitting-world” understanding has only been carried for classical tests [16] and probabilistic branching stemming from measurements [18, 34], and not for quantum superposition. The Quantum Switch can for instance be naturally understood in this framework. Consider for instance Figure 2, read from left to right: as input, a pair of an element of type \(A\) and a quantum bits. Based on the value of the qubit (True or False), the wire \(A\) goes in the upper or the lower sheet, and is fed with \(U\) then \(V\) or \(V\) then \(U\). Then everything is merged back together.

In this paper, we provide a rigorous interpretation for this type of (purely quantum) behavior.

**Contributions** In this paper, we introduce a new graphical language for quantum
computation, based on compact category with biproduct [?]. This language allows us to
to express any quantum process, as we can encode the ZX-Calculus within it. We develop a
denotational semantic and an equational theory, and prove the soundness and completeness
of the semantics. As a case-study, we show how the Quantum Switch can naturally be
encoded in the language.
In the paper, the missing proofs can be found in Appendix.

2 The Many-Worlds Calculus

While the goal is to define a graphical language in which each wire can be enabled or disabled
depending on the world in which the computation takes place, we first define the category
\( C_D \) of diagrams without any "worlds", and will then add the world annotations.

2.1 A First Graphical Language

We define our graphical language within the paradigm of colored PROP [4, 25], meaning
that a diagram will be composed of nodes, or generators, linked to each others through typed
wires, wired that are allowed to cross each others. Additionally, we assume that our colored
PROP is compact closed and auto-dual, meaning that we allow to curve wires to obtain a
Cup or a Cap.

The generators of our language are described in Figure 3 and are respectively the Identity,
the Swap, the Cup, the Cap, the Plus, the Tensor, the Unit, the \( n \)-ary Contraction, and
the Scalar indexed with \( s \) ranging over \( \mathbb{C} \). Mirrored versions of those generators are defined
as syntactic sugar through the compact closure, as shown for the mirrored Plus on the
right-hand-side of Figure 3. Diagrams are read top-to-bottom: the top-most wires are the
input wires and the bottom-most wires are the output wires.

The types of our wires are built from the syntax \( A, B ::= 1 \mid A \oplus B \mid A \otimes B \). The objects
of our category are the set of wires as generated by the grammar \( A, B ::= A \sqcup B \mid \mathbb{C} \mid A \). The
choice of the notation \( \sqcup \) for wires in parallel is uncommon, we use it to put an emphasis on
the fact that contrary to languages like the ZX-calculus, wires that are in parallel are not
necessarily "in tensor with one another". In fact, \( A \sqcup B \) can be understood semantically as
'either \( A \otimes B \) or \( A \oplus B \).

Diagrams are obtained from generators
by composing them in parallel (written \( \sqcup \)),
sequential (written \( \circ \)) as follows. Se-
quential composition requires the (and
number) of wires to match. We write \( C_D \) for the category of diagrams we defined as such.

Example 1. While our language lacks the worlds labeling, we can already illustrate it by
encoding some basic quantum primitive in it and show how they operate. In Figure 4 we
show the encoding of a quantum bit \( \alpha |0\rangle + \beta |1\rangle \) and the Hadamard unitary. In particular,
the Plus allows to "build" a new quantum bit from two scalars in parallel or to "open" a quantum bit to recover its corresponding scalars, the left branch corresponding to $|0\rangle$ and the right branch to $|1\rangle$. The meaning of the Contraction is better seen when applying Hadamard to a quantum bit as we show in Figure 5: it allows us to duplicate and sum scalars. The rewriting sequence of Figure 5 is made using the equational theory defined in Section 4, however to correctly define our equational theory, the worlds labeling are required. So while this specific worlds-free rewriting sequence is sound, many other similar worlds-free rewriting sequences are unsound.

▶ Remark 2. Instead of having the Cup and the Cap as generators and defining the mirrored version of each generator through them, one could proceed the other way around by defining the Cap as follows, and the Cup in a mirrored way:

\[
\begin{align*}
A \& B &:= A \& B \\
A * B &:= A * B \\
1 &:= 1
\end{align*}
\]

2.2 Adding Worlds Labeling

We now label wires of our diagram with worlds sets $w \subseteq W$ for a given a set of worlds $W$. For each world $a \in W$, wires labeled by a set containing $a$ are said to be 'enabled in $a$', and the others are said 'disabled in $a'$. This allows us to correlate the enabling of wires. For example, the 'controlled not' can be represented by the diagram on the right, with worlds $\{a, b, c, \star\}$. The left-hand-side of the diagram forces the world $a$ to correspond to the case where the control qubit is equal to $|0\rangle$, and the worlds $b$ and $c$ when it is equal to $|1\rangle$. The right-hand-side of the diagram applies the identity in the world $a$, and a negation in the worlds $b$ and $c$. Lastly, the world $\star$ appears nowhere in the labels, and corresponds to "we do not evaluate this circuit at all". While not strictly necessary, it is often practical to have a world absent from every wire.

▶ Definition 3. Given a set of worlds $W$, we define the auto-dual compact closed colored PROP $(MW, \square, \square)$ of many-worlds calculus over $W$ as follows:

Its colors are the pairs $(A : w)$ of colors $A$ of $\mathbb{C}_D$ and subsets $w \subseteq W$. We write $(\mathfrak{A}, \ell_A)$ for the objects, where $\mathfrak{A}$ is an object of $\mathbb{C}_D$ and $\ell_A$ is a labeling function from the colors of $\mathfrak{A}$ to the subsets of $W$. 

Figure 3 Generators of our First Graphical Language ($n \geq 0$, $s \in \mathbb{C}$)

\[
\alpha |0\rangle + \beta |1\rangle \leadsto \in \mathbb{C}_D(\mathcal{Z}, I \oplus I) \quad \left(\begin{array}{cc}
\frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \\
\frac{1}{\sqrt{2}} & -\frac{1}{\sqrt{2}}
\end{array}\right) \leadsto \in \mathbb{C}_D(I \oplus I, I \oplus I)
\]

Figure 4 A Quantum Bit and the Hadamard Unitary
The Many-Worlds Calculus: Representing Quantum Control

\[ \frac{1}{\sqrt{2}} - \frac{1}{\sqrt{2}} \rightarrow \frac{1}{\sqrt{2}} \alpha \beta \rightarrow \frac{1}{\sqrt{2}} \alpha \sqrt{2} - \beta \sqrt{2} \alpha \sqrt{2} \beta \rightarrow \alpha + \beta \sqrt{2} \alpha - \beta \sqrt{2} \]

Figure 5 Applying the Hadamard unitary to a quantum bit

Its morphisms \( f : (\mathcal{A}, \ell_\mathcal{A}) \rightarrow (\mathcal{B}, \ell_\mathcal{B}) \) are pairs \((D_f, \ell_f)\) of a morphism \( D_f \in C_D(\mathcal{A}, \mathcal{B}) \) and a labeling function \( \ell_f \) from the wires of \( D_f \) to the subsets of \( W \), satisfying the following constraints: The label on an input or output wire of color \( A : w \) must be equal to \( w \), and

\[
\forall n \geq 0, \quad w_1 \cup \ldots \cup w_n
\]

where \( \sqcup \) denotes a set union which is disjoint. The constraints for the mirrored versions are similar. The sequential composition \( \circ \) and the parallel composition \( \square \) preserve the labels.

Because of the first restriction on labels, given a morphism \( f \), one can infer the labels on its objects from the label \( \ell_f \), hence we can write \( f : \mathcal{A} \rightarrow \mathcal{B} \) instead of \( f : (\mathcal{A}, \ell_\mathcal{A}) \rightarrow (\mathcal{B}, \ell_\mathcal{B}) \) unambiguously. It is discussed in Appendix B.1 how we can compose \( f : \mathcal{A} \rightarrow \mathcal{B} \) and \( g : \mathcal{B} \rightarrow \mathcal{C} \) even when their induced labels do not match.

Example 4 (The Quantum Switch). Given two subdiagrams \( U \) and \( V \), the Quantum Switch of \( U; V \) and \( V; U \) presented in Figure 2 can be encoded as in \( ?? \). The figure is split into two parts: the control part on the left-hand-side, and the computational part on the right-hand-side. The idea is that the control part, that uses \( \oplus \), will behave as an if-then-else and will bind the world \( w \) to the case where the control quantum bit is \( |0\rangle \), and the world \( v \) to the case where the control quantum bit is \( |1\rangle \). On the computational part, \( U \circ V \) will be applied within the world \( v \) while \( V \circ U \) will be applied within the world \( w \). The “sheets" presented in Figure 2 are here modeled with world labels.

For the sake of simplicity, we represented the Quantum Switch here with two copies of \( U \) and \( V \), one for each branch. It is actually possible within our language to share \( U \) and \( V \) between the two worlds in order to only have one copy of each (which is the whole purpose of the Quantum Switch). We describe in Example 8 this “true” Quantum Switch, and one can show using the equational theory given in Section 4 that the two are equivalent.

2.3 Comparison with Other Graphical Languages

We draw some comparison between our language and two other graphical languages: the ZX-Calculus [13], and Duncan’s Tensor-Sum Logic [18].

2.3.1 ZX-Calculus

The first difference is the restrictions of the ZX-calculus to computations between qubits, in other words linear map from \( \mathbb{C}^2^n \rightarrow \mathbb{C}^2^n \), while our language can encode any linear map from \( \mathbb{C}^n \rightarrow \mathbb{C}^n \). The Tensor generator allowing the decomposition of \( \mathbb{C}^2^n \) into instances of \( \mathbb{C}^2 \) was already present in the scalable extension of the ZX-calculus [5], but the main difference comes from the Plus (and the Contraction).
Additionally, every ZX-diagram can be encoded in our graphical language. The identity, swap, cup and cap of the ZX calculus are encoded by the similar generators over the type $\mathbb{1} \oplus \mathbb{1}$, the green spider and Hadamard gate are encoded as described in [25], and an encoding for the red spider can be deduced from those. The worlds set $W$ is equal to $\mathcal{P}(\text{Names})$ where every world node of the ZX-diagram is given a name, and each input and each output of an Hadamard gate is given a name too. For a name $g$, we write $\{a \ni g\} \subseteq W$ for the set $\{a \subseteq \text{Names} \mid g \in a\}$ and $\{a \not\ni g\}$ for its complementary.

### 2.3.2 Tensor-Sum Logic

The core difference between their work and ours is the presence of the contraction in our graphical language. They instead rely on an enrichment of their category by a sum, which they represent graphically with boxes. We show on the right how the morphism $f + g$ would be encoded in both their and our language. More generally, their boxes correspond to uses of our contraction generator in a "well-bracketed" way. Another point of difference is their approach to quantum computation, as we do not assign the same semantics to those superpositions of morphisms. In their approach, the superposition is a classical construction and corresponds to the measurement and the classical control flow, while in our approach the superposition is a quantum construction and corresponds to the quantum control.

## 3 Semantics of the Many-Worlds Calculus

Our calculus aims at pure quantum computations. Following the ZX approach, we relax the condition on unitarity and define a semantics for our Many-World Calculus based on finite dimensional Hilbert spaces and (general) linear operators. More precisely, we will define two semantics, a world-dependent semantics $[-]_a$ for every world $a$, which will be a monoidal functor from $\text{MW}_W$ to $\text{FdHilb}$, and a worlds-agnostic semantics $[-]$ which will not be functorial for the standard sequential composition and parallel composition, though we define in Appendix B.1 the worlds-agnostic sequential composition and parallel composition for which $[-]$ will be functorial.

We start by defining those semantics on the objects. For every object $\mathfrak{A}$ of $\text{C}_\mathbb{D}$, we define its enablings $\mathfrak{A}^*$ as "replacing any number of wire type by $\mathfrak{b}$". For example $(A \square B)^* = \{A \square \mathfrak{b}, B \square \mathfrak{b}, A \square A, B \square B\}$. To each enabling $\mathfrak{c} \in \mathfrak{A}^*$ we associate a Hilbert space $\mathcal{H}_\mathfrak{c}$ as follows: $\mathcal{H}_{A \square \mathfrak{b}} := \mathcal{H}_A \otimes \mathcal{H}_\mathfrak{b}$, $\mathcal{H}_\mathfrak{b} = \mathbb{C}$, $\mathcal{H}_{A \square B} := \mathcal{H}_A \otimes \mathcal{H}_B$, $\mathcal{H}_{A \otimes B} := \mathcal{H}_A \otimes \mathcal{H}_B$.

Then, for any object $(\mathfrak{A}, \ell_\mathfrak{A})$ of $\text{MW}_W$ and any world $a \in W$, we define $(\mathfrak{A}, \ell_\mathfrak{A}) \downarrow a$ to be the enabling of $\mathfrak{A}$ in which every $(A : w)$ with $a \in w$ is preserved and every $(A : w)$ with $a \not\ni w$ is replaced by $\mathfrak{b}$. For example $(A : \{a\} \square B : \{b\}) \downarrow a = A \square \mathfrak{b}$. We can then
The worlds-agnostic semantics is defined from the world-dependent semantics, as follows.

\[
\begin{align*}
\left[ \begin{array}{c}
w \otimes v \\
v \otimes w
\end{array} \right]_a &= \begin{cases} 
\text{Id} & \in \text{FdHilb}(\mathcal{H}_A, \mathcal{H}_A) \quad \text{if } a \in w \setminus v \\
\text{Id} & \in \text{FdHilb}(\mathcal{H}_B, \mathcal{H}_B) \quad \text{if } a \in v \setminus w \\
h \otimes h' \mapsto h' \otimes h & \in \text{FdHilb}(\mathcal{H}_{A \otimes B}, \mathcal{H}_{B \otimes A}) \quad \text{if } a \in w \cap v \\
\end{cases} \\
\in \text{FdHilb}(C, C) & \quad \text{otherwise}
\end{align*}
\]

\[
\begin{align*}
\left[ \begin{array}{c}
w \\
v \otimes w
\end{array} \right]_a &= \begin{cases} 
\text{Id} & \in \text{FdHilb}(\mathcal{H}_A, \mathcal{H}_A) \quad \text{if } a \in w \\
\text{Id} & \in \text{FdHilb}(C, C) \quad \text{otherwise}
\end{cases}
\end{align*}
\]

\[
\begin{align*}
\left[ \begin{array}{c}
w \otimes v \\
w \otimes w
\end{array} \right]_a &= \begin{cases} 
\text{Id} & \in \text{FdHilb}(\mathcal{H}_{A \otimes B}, \mathcal{H}_A) \quad \text{if } a \in w \\
0 & \in \text{FdHilb}(\mathcal{H}_{A \otimes B}, \mathcal{H}_B) \quad \text{if } a \in v \\
\end{cases}
\in \text{FdHilb}(C, C) & \quad \text{otherwise}
\end{align*}
\]

and the (conjugate) transposed operator for the Cup.

\[
\begin{align*}
\left[ \begin{array}{c}
w \otimes v \\
w \otimes w
\end{array} \right]_a &= \begin{cases} 
\text{Id} & \in \text{FdHilb}(\mathcal{H}_A, \mathcal{H}_A) \quad \text{if } a \in w \\
0 & \in \text{FdHilb}(\mathcal{H}_B, \mathcal{H}_B) \quad \text{if } a \in v \\
\end{cases}
\in \text{FdHilb}(C, C) & \quad \text{otherwise}
\end{align*}
\]

and the (conjugate) transposed operator for the mirrored Plus.

**Figure 7** Semantics of the Generators of \( MW_W \) in a World \( a \in W \).

*define the semantics \([-]_a : MW_W \to \text{FdHilb} \) and \([-] : MW_W \to \text{FdHilb} \) on objects as \([\langle A, \ell A \rangle]_a := H(A, A) \otimes A \) and \([\langle A, \ell A \rangle] : = \bigoplus_{c \in A} H(c) \). Then, for the morphisms, we proceed by compositionality for \([-]_a \) meaning that we define \([-]_a \) on every generator and compute the semantics of a diagram by decomposing it with \([g \circ f]_a := [g]_a \circ [f]_a \) and \([f \square g]_a := [f]_a \otimes [g]_a \). When looking at a generator \( gen \in MW_W(\langle A, \ell A \rangle, \langle B, \ell B \rangle) \), in most cases \([\langle A, \ell A \rangle]_a = [\langle B, \ell B \rangle]_a = H \): we then define \([gen]_a \) as the identity of \( \text{Hilb}(H, H) \).

The semantics of the generators are given in Figure 6, for all the other generators their semantics is simply the identity.

The worlds-agnostic semantics is defined from the world-dependent semantics, as follows.

Consider \( f \in MW_W(\langle A, \ell A \rangle, \langle B, \ell B \rangle) \). Then \([f] \in \text{FdHilb} \left( \bigoplus_{c \in A} H(c), \bigoplus_{f \in B} H(f) \right) \) is defined as \([f] := \left\{ \sum_{b \in W} 1 \cdot [f]_a \right\} \in \text{FdHilb}(A \circ B) \), where \( W, A, B, f \) is a shortcut notation for the set \( \left\{ a \in W \mid \langle A, \ell A \rangle \mid a = c \right\} \) and \( \langle A, \ell A \rangle \mid a = f \).

For example, the worlds-agnostic semantics of the Tensor and the Plus are simply the collection of all their world-dependent semantics assembled into a single linear operator:

\[
\begin{align*}
\text{World set: } \{a, \bullet\} &= \begin{bmatrix} \text{Id} & 0 & 0 & 0 \\
0 & \text{Id} & 0 & 0 \\
0 & 0 & \text{Id} & 0 \\
0 & 0 & 0 & \text{Id} \\
\end{bmatrix}
\end{align*}
\]

The worlds-agnostic semantics is universal in the following sense:
The Equational Theory

Similarly to how our semantics is defined in two steps, the equational theory is also defined in two steps:

1. A set of equations within $\text{MW}_W$ for a fixed set of worlds $W$, which will not be complete, but will be sound for $[\cdot]_a$ for every $a \in W$, hence sound for $[\cdot]$ too. We write $\equiv_w$ for the induced congruence\(^1\) over $\text{MW}_W$. We list those equations in Figure 7. Quite notably, the last two rows describe the fact that the contraction is a natural transformation.

2. Five additional equations with side effects on the set of worlds, which will be sound are complete for $[\cdot]$, but not for the $[\cdot]_a$. We write $\equiv$ for the induced equivalence relation, spanning over the morphisms of all the categories $\text{MW}_W$ for $W$ any set of worlds. We have:

   One equation that allows us to rename the worlds: for every morphism $(\mathcal{D}_f, \ell_f)$ of $\text{MW}_W$, and for every bijection $i : W \to V$, we have $(\mathcal{D}_f, \ell_f) \equiv (\mathcal{D}_f, i \circ \ell_f) \in \text{MW}_V$. Two equations

\[^1\text{In other words the smallest equivalence relation satisfying those equations and such that } f \equiv_w f' \implies \forall g, h, l, g \circ (f \square h) \circ k \equiv_w g \circ (f' \square h) \circ k.\]
allowing the annihilation (or creation, when looking at them from right to left) of worlds due to coproducts or scalars (first row of Figure 8); Two equations allowing the splitting (or merging, when looking at them from right to left) of worlds due to coproducts or scalars (second row of Figure 8).

- **Proposition 6** (Soundness). For \( f \) a morphism of \( \text{MW}_W \) and \( g \) of \( \text{MW}_W \), whenever \( f \equiv g \) we have \([f] = [g]\). Additionally if \( W = V \), whenever \( f \equiv_W g \) we have \( \forall a \in W, [f]_a = [g]_a \).

- **Theorem 7** (Completeness). For every \( f : A \to B \) morphism of \( \text{MW}_W \) and \( g : A \to B \) one of \( \text{MW}_V \), \( [f] = [g] \iff f \equiv g \).

The soundness can be proved by a case-by-case analysis on every equation. The completeness theorem follows from the existence of a normal form for \( \equiv \), as described in Section 5.1.

- **Example 8** (The Quantum Switch). As claimed in Example 4, it is possible to represent the Quantum Switch with only one copy of \( U \) and \( V \), and one can rewrite it to the version with two copies of each using the equational theory as shown in Figure 9.

In those diagrams, the worlds set is \( W = w \sqcup v \) and we rely on thick, thin and dotted wires to indicate respectively worlds labels \( w \sqcup v \), \( w \) and \( v \). Each figure has a control side which operates on a quantum bit (type \( \mathbb{I} \oplus \mathbb{I} \)) and binds the world \( w \) to \( |0\rangle \) and the world \( v \) to \( |1\rangle \); and a computational side which operates on some data of an arbitrary type \( A \), on which could be applied \( U \) and/or \( V \) which stand for two morphisms of \( \text{MW}_W(A : W, A : W) \).

The first rewriting step relies on the two lemmas on the right, both of which being deducible from the equational theory (see Appendix A). The second rewriting step is simply using the properties of a compact closed category.
5 Normal Form and Completeness

We can prove that the previous equational theory is complete, by defining a normal form on the morphisms, and by showing that all diagrams can be put in this normal form, which is unique.

5.1 Normal Form

It will be practical for our normal forms to define the following syntactic sugar, which we call the unitor, its unit and its generalized form:

\[ A \quad \equiv \quad \lambda_{11} \quad \lambda_{12} \quad \lambda_{0} \]

We define the short-hand on the right with the assumption that the worlds set is in bijection with the set of scalars, in other words the scalars \( \lambda_{ij}, \lambda_{i}', \lambda_{j}' \) and \( \lambda_{0} \) have for worlds label \( \{a_{ij}\}, \{a_{i}'\}, \{a_{j}'\} \) and \( \{a_{0}\} \) respectively. In particular, all the input (resp. output) wires live in mutually exclusive worlds. An important observation is that any permutation of wires (all mutually exclusive, and of type \( \mathbb{1} \)) can easily be put in this form using the following equations:

The normal form of a morphism \( f : A \rightarrow B \) is defined as the form of the diagram on the left of Figure 10, where the morphism \( \text{iso}_A \) is defined inductively right.

The output wires of \( \text{iso}_A \) for any \( A \) live in mutually exclusive worlds, but once again, we don’t overload the diagrams with unitors or world names encoding this information, although it will be used in the following.

Notice that graphically, there is no difference between \( A \square (B \square C) \) and \( (A \square B) \square C \), in other words \( \square \) is strictly associative. However \( \text{iso}_{\square}(A \square B \square C) \) and \( \text{iso}_A \circ \text{iso}_B \circ \text{iso}_C \) are different, but they are equivalent up to a rearranging of the output wires:

\[ \text{Lemma 9. There exists a wire permutation } \sigma \text{ such that } \text{iso}_{\square}(A \square B \square C) = \sigma \circ \text{iso}_A \circ \text{iso}_B \circ \text{iso}_C. \]
We hence have a choice to make here for canonicity, and choose $\text{iso}_{\mathcal{A}_0 \Box \mathcal{A}_1 \Box \mathcal{A}_2 \Box \ldots} := \text{iso}_A \circ (A_0 \Box A_1 \Box A_2 \Box \ldots)$.

We define $\text{iso}^{-1}_A$ inductively in the same way, but upside-down. We note that $\text{iso}^{-1}_A \circ \text{iso}_A$ is the normal form of $\text{id}_A$.

▶ Proposition 10. The normal form is unique.

5.2 Completeness

We can now use this normal form to show that our equational theory is complete for arbitrary morphisms. To do so, we need to show that all the generators can be put in normal form, and then that any composition of morphisms in normal form can be put in normal form. We do exactly so, and leave the details to the appendix.

▶ Proposition 11. The generators can be put in normal form.

▶ Proposition 12. Compositions of diagrams in normal form can be put in normal form.

This allows us to prove the completeness theorem claimed above:

Proof of Theorem 7. The right-to-left direction of the equivalence can be directly checked by verifying that all the axioms preserve the semantics.

Let $f_1$ and $f_2$ be two morphisms such that $\llbracket f_1 \rrbracket = \llbracket f_2 \rrbracket$. Both morphisms can be put in normal form, resp. $f_1^{NF}$ and $f_2^{NF}$, with $f_1 \equiv f_1^{NF}$ and thus $\llbracket f_1^{NF} \rrbracket = \llbracket f_1 \rrbracket$. By uniqueness of the normal form, and since $\llbracket f_1^{NF} \rrbracket = \llbracket f_2^{NF} \rrbracket$, we get $f_1^{NF} \equiv f_2^{NF}$, which ends the proof that $f_1 \equiv f_2$.

6 Conclusion

We introduced a new sound and complete graphical language based on compact categories with biproducts, along with an equational theory and a worlds system, helping us build a denotational semantics of our language.

This language allows us to generalize already existing quantum graphical languages such as the ZX-calculus with the additions of richer types than just the usual qubits and tensors of qubits. In particular the biproduct allows us to reason about superposition of executions, as shown by the encoding of the Quantum Switch in Example 8.

While our language allows for quantum control, it does not capture another language that aims at formalizing quantum control, namely the PBS-Calculus [10]. How and in which context could we capture the PBS-Calculus is left for future work.

We include in this section a few practical lemmas that are provable from the equational theory $\equiv_W$.

**Lemma 13.** Whenever $w_i$ are disjoint sets of worlds, we have the following:

$\equiv_W$

**Lemma 14.** Whenever $w_i$ are disjoint sets of worlds, and that the $v_i$ are disjoint sets of worlds too, we have the following:

$\equiv_W$

**Proof.** We provide a proof for the third equation, the first two are proven similarly.
Corollary 15. For every \( f : \Box^n(A_i : w_i) \rightarrow \Box^m(B_j : v_j) \) with worlds set \( W \) and every \( u \subseteq W \), we have

\[
\begin{array}{c}
\begin{array}{c}
w_1 \setminus u \\
\vdots \\
w_n \setminus u \\
w_1 \cap u \\
w_n \cap u
\end{array}
\end{array}
\]

\[\equiv W\]

where \( f \setminus u : \Box^n(A_i : w_i \setminus u) \rightarrow \Box^m(B_j : v_j \setminus u) \) is equal to \( f \) where every worlds label \( w \) has been replaced by \( w \setminus u \), and similarly for \( f \cap w \).

This is simply proven by induction over \( f \). All the generator cases (including Cup and Cap) follow directly from the equations given in Figure 7 an Lemma 14 together with the properties of a compact close category.

Lemma 16. For every \( f : \Box^n(A_i : \emptyset) \rightarrow \Box^m(B_j : \emptyset) \) with worlds set \( W \) but such that every worlds label of \( f \) is \( \emptyset \), we have

\[
\begin{array}{c}
\begin{array}{c}
\emptyset \\
\vdots \\
\emptyset
\end{array}
\end{array}
\]

\[\equiv W\]

This is simply proven by replacing every wire by two contractions of arity zero (sixth axiom of Figure 7 with \( n = 0 \)), and then using the naturality of the contraction of arity zero (last two lines of Figure 7 with \( n = 0 \)) to consume every generator.

B. Dealing with Worlds Labeling

The worlds labeling can appear to be a very strict structure making it unpractical to manipulate diagrams. In this appendix, we show a number of tools that allow to manipulate worlds labeling in a more flexible way.

B.1 Worlds-Agnostic Category

In this section, we define the category \( \text{MW}_W \) which has the same objects as \( \text{CD} \), so no worlds labeling on the objects, and has for morphisms all the morphisms of the categories \( \text{MW}_W \) for every worlds set \( W \). In other words, we explain how to make sequential composition and parallel composition of morphisms that have different worlds set.

We write \([f]_W : \mathcal{A} \rightarrow \mathcal{B}\) for a morphism \((D_f, \ell_f) \in \text{MW}_W((\mathcal{A}, \ell_\mathcal{A}), (\mathcal{B}, \ell_\mathcal{B}))\), where \( \ell_\mathcal{A} \) and \( \ell_\mathcal{B} \) are the labeling induced on \( \mathcal{A} \) and \( \mathcal{B} \) by \( \ell_f \).

The goal of this section is to allow to compose \([f]_W : \mathcal{A} \rightarrow \mathcal{B}\) and \([g]_V : \mathcal{B} \rightarrow \mathcal{C}\) even when the inferred labels on \( \mathcal{B} \) do not match and when \( W \) and \( V \) are different.
\[ W = \{a, *\} \quad V = \{b, *\} \quad W \times V = \{(a, b), (a, *), (*, b), (*,*)\} \]

\[
\begin{array}{c|c|c}
\{a\} & \square & \{b\} \\
\hline
\{(a, b), (a,*)\} & \square & \{(a, b), (*, b)\}
\end{array}
\]

Figure 12 Example of Worlds-Agnostic Parallel Composition

B.1.1 Extending the Worlds Set

Before tackling the sequential composition, we start by defining the parallel composition between morphisms with different world sets. For \(W, V\) two sets of worlds, and for \(f : S \rightarrow W\), we define \(\ell^{-\times V} : S \rightarrow W \times V\) as \(\ell^{-\times V}(s) = \{(a, b) \mid a \in \ell(s), b \in V\}\). Similarly, for \([f]_W : \mathfrak{A} \rightarrow \mathfrak{B}\), we define \([f^{-\times V}]_{W \times V}\) as the morphism \((D_f, \ell^{-\times V})\). We define \(\ell^{-\times V}\) and \(f^{-\times V}\) symmetrically.

**Definition 17** (Worlds-Agnostic Parallel Composition). For \([f]_W : \mathfrak{A} \rightarrow \mathfrak{B}\) and \([g]_V : \mathfrak{C} \rightarrow \mathfrak{D}\) two morphisms, we define

\[ [f]_W \bigcirc [g]_V := [f^{-\times V} \bigcirc g^{-\times V}]_{W \times V} : (\mathfrak{A} \bigcirc \mathfrak{B}) \rightarrow (\mathfrak{C} \bigcirc \mathfrak{D}) \]

In Figure 11, we show the result of this parallel composition when \([f]_{(a, *)} = \text{id}_{A \{a\}}\) and \([g]_{(b, *)} = \text{id}_{A \{b\}}\) for a color \(A\).

B.1.2 Restricting the Worlds Set

We now tackle the sequential composition. For \(W\) a set of worlds, \(w \subseteq W\), we define the restriction of \(\ell : S \rightarrow W\) to \(W \setminus w\) written \(\ell^{\setminus w} : S \rightarrow W \setminus w\) as \(\ell^{\setminus w}(s) = \{a \in \ell(s) \mid a \notin w\}\). For \([f]_W : \mathfrak{A} \rightarrow \mathfrak{B}\) we define \([f^{\setminus w}]_{W \setminus w} : \mathfrak{A} \rightarrow \mathfrak{B}\) as the morphism \((D_f, \ell^{\setminus w})\).

**Definition 18.** Given two morphisms \(\mathfrak{f} : (A, \ell_A) \rightarrow (B, \ell_B)\) and \(\mathfrak{g} : (B, \ell_B) \rightarrow (C, \ell_C)\), we write \(w\) for the smallest subset of \(W \times V\) such that \((f^{-\times V})^\setminus w\) induces the same worlds labeling on \(\mathfrak{B}\) as \((g^{-\times V})^\setminus w\). We then define

\[ [g]_V \circ [f]_W := [(g^{-\times V})^\setminus w \circ (f^{-\times V})^\setminus w]_{(W \times V) \setminus w} \]

We continue the previous example in Figure 12 by composing the result with the Cup over \(A : \{c, *\}\). We proceed in two steps: first we handle the situation as if it was a parallel composition, leading to a diagram labeled over \(W \times V \times U\), but with multiple contradictory labels on the wire. Then, we eliminate as few worlds as possible to make those labels compatible:

- We eliminate \((a, b, *)\) and \((a, *, *)\) which are on the left label but not on the bottom one.
- We eliminate \((*, b, c)\) and \((*, *, c)\) which are on the bottom label but not on the left one.
- We eliminate \((*, b, *)\) which is on the right label but not on the bottom one. We would also eliminate \((a, b, *)\) if we had not done so already.
- We eliminate \((a, *, c)\) which is on the bottom label but not on the right one. We would also eliminate \((*, *, c)\) if we had not done so already.

The eliminated worlds are \(w = \{(a, b, *), (a, *, c), (*, b, c), (a, *, *), (*, b, *), (*, *, c)\}\), and what remains is \(\{(a, b, c), (*, *, *)\}\).
The functoriality with respect to the parallel composition is then immediate:

\[ W \times V = \{(a, b), (a, \star), (\star, b), (\star, \star)\} \]

\[ W \times V \times U = \{(a, b, c), (a, b, \star), (a, \star, c), (a, \star, \star), (\star, b, c), (\star, b, \star), (\star, \star, c), (\star, \star, \star)\} \]

\[ \text{(}W \times V \times W\text{)} \setminus w = \{(a, b, c), (\star, \star, \star)\} \]

The functoriality with respect to the sequential composition is more subtle, as one must carefully manipulate the indices of the sum and remark that the set of worlds

\[ U = \{c, \star\} \]

\[ (a, b, \star) \]

\[ \text{(a, b, c)} \]

\[ \text{(a, \star, c)} \]

\[ \text{(\star, b, c)} \]

\[ \text{(\star, \star, c)} \]

\[ \text{(\star, \star, \star)} \]

\[ \text{Example of Worlds-Agnostic Sequential Composition} \]

\[ \text{Figure 13} \]

\[ \text{B.1.3 The Worlds-Agnostic Category and its Semantics} \]

\[ \text{MW}_v \text{ with the sequential and parallel composition as described above forms a category (up to renaming of worlds), and is in fact an auto-dual compact closed colored PROP (up to renaming of worlds).} \]

\[ \text{Proposition 19. The worlds-agnostic semantics } [-] \text{ defined in Section 3 is a monoidal functor from } \text{MW}_v \text{ to } FdHilb.} \]

\[ \text{Proof. We recall here the definition of the worlds-agnostic semantics of } [f]_W : \mathfrak{A} \rightarrow \mathfrak{B}: \]

\[ [[f]_W] := \left\{ \sum_{a \in W} [[f]_a] \right\} \]

\[ \text{From the definition of the worlds-agnostic compositions, we directly have:} \]

\[ [[f]_W \Box [g]_V]_{(a, b)} = [[f]_W]_a \bowtie [[g]_V]_b \quad [[g]_V \circ [f]_W]_{(a, b)} = [[g]_V]_b \circ [[f]_W]_a \]

The functoriality with respect to the parallel composition is then immediate:

\[ [[f]_W \Box [g]_V] = \left\{ \sum [[f]_W \Box [g]_V]_{(a, b)} \right\} = \left\{ \sum [[f]_W]_a \right\} \bowtie \left\{ \sum [[g]_V]_b \right\} = [[f]_W] \bowtie [[g]_V] \]

The functoriality with respect to the sequential composition is more subtle, as one must carefully manipulate the indices of the sum and remark that the set of worlds \( w \) eliminated by the worlds-agnostic composition satisfies the following:

\[ (a, b) \notin w \iff (\mathfrak{B}, \ell^f_\mathfrak{B}) \downarrow a = (\mathfrak{B}, \ell^g_\mathfrak{B}) \downarrow b \text{ where } f : (\mathfrak{A}, \ell^f_\mathfrak{A}) \rightarrow (\mathfrak{B}, \ell^A_\mathfrak{B}) \]

\[ g : (\mathfrak{B}, \ell^f_\mathfrak{B}) \rightarrow (\mathfrak{C}, \ell^g_\mathfrak{B}) \]

Then, we have

\[ [[g]_V \circ [f]_W] = \left\{ \sum [[g]_V \circ [f]_W]_{(a, b)} \right\} = \left\{ \sum [[g]_V]_b \right\} \circ \left\{ \sum [[f]_W]_a \right\} = [[g]_V] \circ [[f]_W] \]
B.2 Keeping the Worlds Labeling Implicit

In Figure 5, we provide an example where one can use the equational theory without the worlds. In the previous section, we provided a worlds-agnostic semantics to our diagrams. It is reasonable to wonder how much can be done within \( C_D \), in other words without using the worlds labeling. In the following, we show how to provide a canonical labeling for diagrams of \( C_D \) and deduce a denotational semantics for \( C_D \).

We consider a diagram \( D \) of \( C_D \) and we want to define a canonical worlds labeling over its set of wires \( W \). The core idea is that a world will be a set of wires that can cohabit with each others while satisfying the constraints of the nodes Plus, Tensor, etc. For example in Figure 13, there are four wires with wire 1 and 2 being incompatible due to the Plus, but also inseparable from wire 3, hence the canonical worlds set would be:

\[
\emptyset, \{1, 3\}, \{2, 3\}, \{4\}, \{1, 3, 4\}, \{2, 3, 4\}\]

More formally, a subset of wires \( S \subseteq W \) is said valid if the labeling \( \ell_S : x \mapsto \{\ast\} \) if \( x \in S \) and \( \emptyset \) otherwise is a valid labeling for \( D \), in other words if \( (D, \ell_S) \) is a morphism of \( MW_{\{\ast\}} \).

We will take for worlds set \( W_D \subseteq P(W) \) the sets of valid subsets of wires. The labeling will simply be: \( \ell_D : x \mapsto \{S \in V \mid x \in S\} \).

\begin{itemize}
  \item \textbf{Proposition 20.} For every diagram \( D \) of \( C_D \), \( (D, \ell_D) \) is a morphism of \( MW_{\{\ast\}} \). Up to renaming of the worlds, this construction is a monoidal functor from \( C_D \) to \( FdHilb \).
\end{itemize}

It follows that if we define \( [D] \) as \( [(D, \ell_D)] \), this semantics is a monoidal functor from \( C_D \) to \( FdHilb \). We note that it is enough to compute the semantics of the generators of \( C_D \) (see FIGURE) to obtain the semantics for every diagram using \( [D \circ D'] = [D] \circ [D'] \) and \( [D \boxtimes D'] = [D] \otimes [D'] \).
**C** Proofs of Universality and Uniqueness of Normal Form

**Universality**

In this section, we show that for every $\mathfrak{A}, \mathfrak{B}$ objects of $C_D$, and for every linear operator

$$\Lambda = \begin{pmatrix}
\lambda_{11} & \cdots & \lambda_{1n} \\
\vdots & \ddots & \vdots \\
\lambda_{m1} & \cdots & \lambda_{mn}
\end{pmatrix} \in \text{EndHib} \left( \bigoplus_{e \in \mathfrak{A}} \mathcal{H}_e, \bigoplus_{f \in \mathfrak{B}} \mathcal{H}_f \right)$$

then the morphism $f = \text{iso}_\mathfrak{B}^{-1} \circ \lambda \circ \text{iso}_\mathfrak{A}$ defined in Figure 10 satisfies $[f] = \Lambda$.

As stated in the corresponding section, there is one world for each scalar in $\lambda$, so we write $a_{ij}$ the world associated to $\lambda_{ij}$ and $a_i', a_j', a_0$ similarly, and $W$ the set of all those worlds.

Writing $e^k$ for $\bullet \Box \ldots \Box \bullet$ (with $k$ elements) and $1^k_i$ for $e^k$ where the $i$-th $\bullet$ has been replaced by $1$, we have the following:

$$\begin{align*}
[\lambda]_{a_{ij}} : 1^m_i \to 1^m_j : x &\mapsto \lambda_{ij} \cdot x \\
[\lambda]_{a_i'} : 1^m_i \to \bullet^m_i : x &\mapsto \lambda_{i} \cdot x \\
[\lambda]_{a_j'} : \bullet^m_i \to 1^m_j : x &\mapsto \lambda_{ij}'' \cdot x \\
[\lambda]_{a_0} : \bullet^m_i \to \bullet^m_j : x &\mapsto \lambda_{0} \cdot x
\end{align*}$$

Additionally, one can show by induction that $[\text{iso}_\mathfrak{A}]_{a_{ij}}$ and $[\text{iso}_\mathfrak{A}]_{a_i'}$ (resp. $[\text{iso}_\mathfrak{A}]_{a_j'}$ and $[\text{iso}_\mathfrak{A}]_{a_0}$) are simply the projection on the $i$-th (resp. $(n + 1)$-th) element of the canonical basis, and $[\text{iso}_\mathfrak{B}]_{a_{ij}}$ and $[\text{iso}_\mathfrak{B}]_{a_i'}$ (resp. $[\text{iso}_\mathfrak{B}]_{a_j'}$ and $[\text{iso}_\mathfrak{B}]_{a_0}$) are simply the injection on the $j$-th (resp. $(m + 1)$-th) element of the canonical basis. Since we have $[f]_a = [\text{iso}_\mathfrak{B}]_{a'} \circ [\lambda]_a \circ [\text{iso}_\mathfrak{A}]_a$ for every $a \in W$, and $[f]$ being the collection of all the $[f]$, we obtain that $[f] = \Lambda$.

**Uniqueness of Normal Form**

Let $f$ and $g$ be two diagrams in normal form (with respectively $\lambda$ and $\mu$ as inner block), such that $[f] = [g]$ (the naming of the worlds is taken to be the same in both diagrams, and is the same as in the previous proof). By the definition of $[\cdot]$, we have $[f]_a = [g]_a$ for every $a \in W$. We hence have $[\text{iso}_\mathfrak{B}]_a \circ [\lambda]_a \circ [\text{iso}_\mathfrak{A}]_a = [\text{iso}_\mathfrak{B}]_a \circ [\mu]_a \circ [\text{iso}_\mathfrak{A}]_a$.

Denoting $e^i_\mathfrak{A}$ (resp. $e^i_\mathfrak{B}$) the $i$-th element of the basis of $\mathfrak{A}$ (resp. $\mathfrak{B}$), we have:

$$\begin{align*}
\lambda_{ij} &= e^j_\mathfrak{B} \circ [\text{iso}_\mathfrak{B}]_{a_{ij}} \circ [\lambda]_{a_{ij}} \circ [\text{iso}_\mathfrak{A}]_{a_{ij}} e^i_\mathfrak{A} = e^j_\mathfrak{B} \circ [\text{iso}_\mathfrak{B}]_{a_{ij}} \circ [\mu]_{a_{ij}} \circ [\text{iso}_\mathfrak{A}]_{a_{ij}} e^i_\mathfrak{A} = \mu_{ij} \\
\lambda_i' &= e^i_\mathfrak{B} \circ [\text{iso}_\mathfrak{B}]_{a_i'} \circ [\lambda]_{a_i'} \circ [\text{iso}_\mathfrak{A}]_{a_i'} e^i_\mathfrak{A} = e^i_\mathfrak{B} \circ [\text{iso}_\mathfrak{B}]_{a_i'} \circ [\mu]_{a_i'} \circ [\text{iso}_\mathfrak{A}]_{a_i'} e^i_\mathfrak{A} = \mu_i' \\
\lambda_j'' &= e^j_\mathfrak{B} \circ [\text{iso}_\mathfrak{B}]_{a_j''} \circ [\lambda]_{a_j''} \circ [\text{iso}_\mathfrak{A}]_{a_j''} e^j_\mathfrak{A} = e^j_\mathfrak{B} \circ [\text{iso}_\mathfrak{B}]_{a_j''} \circ [\mu]_{a_j''} \circ [\text{iso}_\mathfrak{A}]_{a_j''} e^j_\mathfrak{A} = \mu_j'' \\
\lambda_0 &= e^0_\mathfrak{B} \circ [\text{iso}_\mathfrak{B}]_{a_0} \circ [\lambda]_{a_0} \circ [\text{iso}_\mathfrak{A}]_{a_0} e^0_\mathfrak{A} = e^0_\mathfrak{B} \circ [\text{iso}_\mathfrak{B}]_{a_0} \circ [\mu]_{a_0} \circ [\text{iso}_\mathfrak{A}]_{a_0} e^0_\mathfrak{A} = \mu_0
\end{align*}$$

where $|\mathfrak{B}|$ denotes the number of wires in $\mathfrak{B}$.

Hence, all coefficients in the scalars of $f$ and $g$ are the same. Since the structure is otherwise the same for $f$ and $g$, they are the same diagram.
Given that most of the time, $\text{gen}^a$ is the identity, the equations defining $\equiv_W$ are quite straightforward to verify. We immediately have that $\equiv_W$ is sound with respect to $\equiv_a$ for every $a \in W$. Since $\equiv$ is defined from $\equiv_a$, soundness with respect to $\equiv$ is also correct.

We then handle the five additional equations of $\equiv$.

Renaming Applying a bijection to the worlds set $W$ does not change the result computed by $\sum_{a \in W} \ldots$, hence this equation is sound with respect to $\equiv$.

Annihilation due to Scalars This equation simply removes elements equal to zero from the sum $\sum_{a \in W} \ldots$, hence it is sound with respect to $\equiv$.

Annihilation due to Plus Since $\oplus$ is a biproduct in FdHilb, we have $\text{proj}_H^{\oplus K} \circ \text{inj}_H^{\oplus K} = \text{id}_H$, $\text{proj}_K^{\oplus K} \circ \text{inj}_K^{\oplus K} = \text{id}_K$, $\text{proj}_K^{\oplus K} \circ \text{inj}_H^{\oplus K} = 0$ and $\text{proj}_H^{\oplus K} \circ \text{inj}_K^{\oplus K} = 0$. One can then simply remove from the $\sum_{a \in W} \ldots$ the elements equal to zero, which proves that Annihilation due to Plus is sound with respect to $\equiv$.

Splitting due to Scalars Since FdHilb is a vector space, we have $(s + t) \cdot f = s \cdot f + t \cdot f$, which is exactly the property required for this equation to be sound for $\equiv$.

Splitting due to Plus Similarly, we have in FdHilb the property that $\text{id}^{\oplus K} = \text{inj}_H^{\oplus K} \circ \text{proj}_H^{\oplus K} + \text{inj}_K^{\oplus K} \circ \text{proj}_K^{\oplus K}$, which is the property required for this equation to be sound for $\equiv$.
E. Proofs for Completeness

E.1 The Normal Form

Proof of Lemma 9. First notice that in both $\text{iso}_A □ (B □ C)$ and $\text{iso}_A □ B □ C$, we can use the bialgebra between contractions and unitors, followed by their respective fusions in the following way:

\[ \text{iso}_A □ (B □ C) \equiv \text{iso}_A □ B □ C \]

and similarly for $\text{iso}_A (A □ B) □ C$. It then suffices to check which contractions the bottom unitors are linked to. Naming the $i$th contraction existing $\text{iso}_A$ as $a_i$, and similarly for $B$ and $C$, we can see that for each triple $(a_i, b_j, c_k)$ there is exactly one unitor connected to precisely contraction $a_i$, $b_j$ and $c_k$, in both diagrams. The same is true for every pair $(a_i, b_j)$, $(a_i, c_k)$ and $(b_j, c_k)$, as well as for every 1-tuple $(a_i)$, $(b_j)$ and $(c_k)$. This shows that both diagrams are equal up to rearranging of the outputs.

\[ \text{Lemma 21.} \quad \text{Notice that } \text{iso}_{A □ B} \equiv \text{iso}_A □ B \quad \text{and } \quad \text{iso}_{A ⊗ B} \equiv \text{iso}_A □ B . \]

\[ \text{Lemma 22.} \quad \text{We have the following identities:} \]

\[ \text{iso}_A □ B \equiv \mathcal{A} \quad \text{and} \quad \text{iso}_A □ B \equiv \mathcal{A} \quad \text{where } \ell(s_i) \cap \ell(s_j) = \emptyset \text{ when } i \neq j. \]

Proof of Lemma 22. We will use the following identities:

\[ \begin{align*}
\text{iso}_A □ B & \equiv \mathcal{A} \quad \text{and} \quad \text{iso}_A □ B \equiv \mathcal{A} \\
\text{iso}_A □ B & \equiv \mathcal{A} \quad \text{where } \ell(s_i) \cap \ell(s_j) = \emptyset \text{ when } i \neq j.
\end{align*} \]

We can show this result by induction on $n$ and $m$. Case $(0, m)$ is obvious. Case $(1, 1)$ can be proven easily using worlds sets:
For any $n$ and $m$, we can then prove the case $(n + 1, m)$ using the cases $(n, m)$ and $(1, m)$ (the case $(n, m + 1)$ is completely symmetric):

In a similar way, it is possible to show the following three identities:
\[ \text{iso}_A \circ \text{iso}_B \]: The result is obvious in cases 1 and \( \overline{3} \). For \( A \oplus B \):

\[ \begin{array}{c}
\text{iso}_A \\
\text{iso}_B \\
\text{iso}_A \\
\text{iso}_B \\
\ldots
\end{array}
\begin{array}{c}
\text{iso}_A \\
\text{iso}_B \\
\text{iso}_A \\
\text{iso}_B \\
\ldots
\end{array}
\equiv
\begin{array}{c}
\text{iso}_A \\
\text{iso}_B \\
\text{iso}_A \\
\text{iso}_B \\
\ldots
\end{array}
\begin{array}{c}
\text{iso}_A \\
\text{iso}_B \\
\text{iso}_A \\
\text{iso}_B \\
\ldots
\end{array}
\begin{array}{c}
\text{iso}_A \\
\text{iso}_B \\
\text{iso}_A \\
\text{iso}_B \\
\ldots
\end{array}
\begin{array}{c}
\text{iso}_A \\
\text{iso}_B \\
\text{iso}_A \\
\text{iso}_B \\
\ldots
\end{array}
\end{array} \]

The proof is similar for \( \otimes \) and \( \square \) using the previous identities.

\[ \text{iso}_A \circ \text{iso}_A \]: The result is again obvious for 1 and \( \overline{3} \). The general result is easy to prove by induction using the above identities.

\section*{E.2 The Completeness}

We want to show here the results of Section 5.2. To do so we will first derive a few lemmas:

\begin{itemize}
  \item \textbf{Corollary 23} (of Corollary 15).
  \begin{itemize}
    \item Single-colored isos distribute over the contraction:
    \begin{itemize}
      \item \text{ iso }_A \equiv \text{ iso }_A \text{ iso }_A
      \item \text{ iso }_A \equiv \text{ iso }_A \text{ iso }_A
    \end{itemize}
  \end{itemize}
  \begin{itemize}
    \item when \( s_1 \cap s_4 = s_2 \cap s_3 = \emptyset \)
  \end{itemize}

  \item \textbf{Corollary 24} (of Corollary 15).
  \begin{itemize}
    \item Scalars distribute over single-colored isos:
    \begin{itemize}
      \item \text{ iso }_A \equiv \text{ iso }_A \text{ iso }_A
      \item \text{ iso }_A \equiv \text{ iso }_A \text{ iso }_A
    \end{itemize}
  \end{itemize}

  \item \textbf{Lemma 25}.
  \begin{itemize}
    \item \text{ iso }_A \equiv \text{ iso }_A \text{ iso }_A
    \item \text{ iso }_A \equiv \text{ iso }_A \text{ iso }_A
  \end{itemize}
\end{itemize}

\begin{itemize}
  \item \textbf{Proof}. The result is obvious for 1 and \( \overline{3} \). For \( A \oplus B \):
  \begin{itemize}
    \item \text{ iso }_A \text{ iso }_B \equiv \text{ iso }_A \text{ iso }_B \text{ iso }_A \text{ iso }_B \equiv \text{ iso }_A \text{ iso }_B \text{ iso }_A \text{ iso }_B \\
    \item For \( A \otimes B \):
    \begin{itemize}
      \item \text{ iso }_A \text{ iso }_B \equiv \text{ iso }_A \text{ iso }_B \text{ iso }_A \text{ iso }_B \equiv \text{ iso }_A \text{ iso }_B \text{ iso }_A \text{ iso }_B \\
    \end{itemize}
  \end{itemize}
\end{itemize}
Corollary 26 (of Corollary 15).

\[ \lambda \quad | \quad \mu \]

with \( s_0 \cap s_1 = \emptyset \).

Corollary 27 (of Lemma 13).

\[ \lambda \quad | \quad \mu \]

Corollary 28 (of Lemma 13).

\[ \lambda \quad | \quad \mu \]

Lemma 29.

\[ \lambda \quad | \quad \mu \]

with \( \nu_{ij} = \sum_k \lambda_k \mu_{kj} + \lambda'_j \mu''_j, \nu'_i = \sum_k \lambda_k \mu_{ki} + \lambda_0 \mu''_k \)

\[ \nu''_i = \sum_k \lambda''_k \mu''_k \]

\[ \nu_0 = \lambda_0 \mu_0 + \sum_k \lambda''_k \mu''_k. \]

Proof. Consider first the following simpler case:

\[ \lambda \quad | \quad \mu \]

Importantly, in the last diagram, we have that each internal wire lives in a set of worlds that has empty intersection with any of the others. It is hence possible to rename this set of worlds to a singleton, and to do it for each internal wire.

For the general case, it is important to properly look at the worlds. Denoting \( w^{\lambda}_{ij} \) the (singleton) world that bears \( \lambda_{ij} \), \( w^{\lambda'}_{i} \) the one that bears \( \lambda'_{i} \), \( w^{\lambda''}_{i} \) the one that bears \( \lambda''_{i} \) and \( w^{\mu}_{0} \) the one that bears \( \mu_{0} \) in matrix block \( \lambda \), and similarly in matrix block \( \mu \), we get:

\[ \lambda \quad | \quad \mu \]

\[ \sum_{\lambda_k \mu_{kj}} \]
where $a^* w^b = \{(z_1, z_2) \mid z_1 \in w^a, z_2 \in w^b\}$. Let us now look at how to push the middle dangling wires through. At the first junction, we have:

$$
\begin{align*}
\bigcup_{i \in I} \lambda_i \omega^\mu_{11} \cup \lambda_i \omega^\mu_{12} \\
\bigcup_{i \in I} \lambda_i \omega^\mu_{21} \cup \lambda_i \omega^\mu_{22} \\
\bigcup_{i \in I} \lambda_i \omega^\mu_{31} \cup \lambda_i \omega^\mu_{32} \\
\bigcup_{i \in I} \lambda_i \omega^\mu_{41} \cup \lambda_i \omega^\mu_{42}
\end{align*}
$$

Doing this at every junction wire, we are able to push all the middle dangling wires to the boundaries, and where the middle is in the shape of the previous simple case (2).

Let us now look at the boundaries, for instance the first output. After pushing all dangling wires, and taking into account the scalar diagram $\lambda_0$, we have:

$$
\begin{align*}
\bigcup_{i \in I} \lambda_i \omega^\mu_{11} \cup \lambda_i \omega^\mu_{12} \\
\bigcup_{i \in I} \lambda_i \omega^\mu_{21} \cup \lambda_i \omega^\mu_{22} \\
\bigcup_{i \in I} \lambda_i \omega^\mu_{31} \cup \lambda_i \omega^\mu_{32} \\
\bigcup_{i \in I} \lambda_i \omega^\mu_{41} \cup \lambda_i \omega^\mu_{42}
\end{align*}
$$

where on the right hand side of the diagram, we decomposed the dangling wire by its different elementary worlds. One of them was shared with the $\lambda_0$ scalar, and using Lemmas 27 and 28, we could bring them together. Then on the left hand side, we used the fact that none of the $\lambda_i \omega^\mu_{11}$ nor the $\lambda_i \omega^\mu_{21}$ could be found elsewhere in the diagram, so we could sum all the scalars without altering the rest of the diagram.

Doing so for all boundaries, scalars $\lambda_0$ and $\mu_0$ are only left on world $\lambda_0 \omega^\mu_{00}$. We can then use Lemma 28 to bring them together. All the worlds on right hand side of the last diagram above $\lambda_i \omega^\mu_{11}$ can be found on the boundaries at the top (i.e. for each input $i$ and output $j$ there is world $\lambda_i \omega^\mu_{ij}$ shared between the two). Using the small following derivation, we can bring them together:

$$
\begin{align*}
\bigcup_{i \in I} \lambda_i \omega^\mu_{11} \equiv \bigcup_{i \in I} \lambda_i \omega^\mu_{12} \equiv \bigcup_{i \in I} \lambda_i \omega^\mu_{13} \equiv \lambda_0 \omega^\mu_{00}
\end{align*}
$$

Now this world can be found nowhere else in the diagram, it is hence possible to sum the scalar with the other that has the same neighbourhood, obtained from (2).
It remains to deal with the scalars. We have $\lambda_0\mu_0$ on world $\lambda_0\mu_0$ from what we just discussed. We also have scalar $\lambda''\mu''$ on world $\lambda''\mu''$ from the dangling wires at the junction. All these worlds are again mutually exclusive and found nowhere else in the diagram. We can hence sum them and get $\lambda_0\mu_0 + \sum_i \lambda'' \mu''$ as the scalar on the side. After all this, the diagram is in the appropriate form (up to renaming of worlds), with all worlds in the internal wires being mutually exclusive.

Lemma 30. For any "matrix block" $\lambda$, there exists a "matrix block" $\nu$ such that:

$$\lambda = \nu$$

Proof. We show the result through several steps. First we show the following:

$$= \equiv \equiv$$

Then, we deal with the top dangling scalars and prove that:

$$\equiv \equiv \equiv$$

Indeed:

$$\equiv \equiv \equiv$$

This case generalizes to any bottom wire the dangling scalar is applied on. When we have several of them, we can make them go through the top part in turns, then aggregate them under a single "matrix block" using Lemma 29.

We then derive the following equation:
We can finally prove the lemma:

\[
\lambda \equiv \cdots \cdots \cdot \cdots
\]

\[
\cdots \cdots \cdot \cdots \equiv (4)
\]

\[
\nu' \equiv \cdots \cdots \cdot \cdots \equiv (5)
\]

\[
\nu \equiv \cdots \cdots \cdot \cdots \equiv 29
\]

We can now move on to show that generators can be put in normal form:

Proof of Proposition 11.
with $\sigma$ a simple permutation of wires.

The upside-down versions of the generators are provided in exactly the same way (but upside-down).

And then that compositions of diagrams in normal form can be put in normal form:

**Proof of Proposition 12.** In the case of sequential composition:
In the case of parallel composition:

\[
\begin{array}{c}
\text{iso} A \square C \\
\text{iso} B \square D \\
\text{iso} B \square D \\
\text{iso} A \square C
\end{array}
\]

where \( \square \) represents the canonical choice of composition with \( \square \) (and similarly for \( B \square D \)).
