HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
PULSED NMR EXPERIMENTS ON \textit{AuIn$_2$} WITH RESPECT TO ITS PERFORMANCE AS A NUCLEAR REFRIGERANT

Abstract.— The dynamic properties of $^{115}\text{In}$ spins in $\text{AuIn}_2$ were studied with pulsed NMR in fields of 74.3 mT and 38.5 mT down to 25 mK. From the measured spin-spin correlation time a nuclear ordering temperature of 1.1 mK is deduced. The spin-lattice relaxation time is found to be field dependent but still an order of magnitude shorter than that of Cu. The advantages of $\text{AuIn}_2$ as a nuclear refrigerant are discussed.

A typical result for the amplitude of the FIS is shown in figure 1. It is obvious that the decay is not a simple exponential. The extreme values of $T_2$ are 15 (1) $\mu$s and 44 (3) $\mu$s (dashed lines). This behaviour is found to be independent of $T$ and $H_0$ and can neither be attributed to inhomogeneities of $H_0$ nor to transients of the coil system itself. We observed, however, that the contribution of the faster decay to the signal decreased rapidly with increasing pulse length, i.e. narrower bandwidth around the Larmor frequency. Therefore,

Fig. 1: Free Induction Signal of $^{115}\text{In}$ in $\text{AuIn}_2$ at $H_0 = 74.3$ mT and $T=25$ mK : tipping angle is 64° corresponding to maximum transverse magnetization. The data can be fitted by two time constants (dashed lines).

With In as nuclear refrigerant a higher cooling power and a shorter thermal response time should be possible than with Cu which is normally used. However, the quadruple interaction as well as the high critical field $H_{\text{co}}$ limits the application of In at temperatures $T>0.1$ mK. Lower $T$, though, should be obtainable in the alloy $\text{AuIn}_2$ where the In atoms are located in cubic symmetry and which has a $H_{\text{co}}$ as low as 1.66 mT /1/.

In view of this aspect we have performed pulsed NMR experiments on $^{115}\text{In}$ in $\text{AuIn}_2$ at two magnetic fields $H_0$ or 74.3 mT and 38.5 mT and in a temperature range from 25 mK to 100 mK. From the free induction decay (FIS) the spin-spin correlation time $T_2$ is determined which is inversely proportional to the spontaneous ordering temperature of the system. Also the spin-lattice relaxation time $T_1$ was measured in order to verify the small Korringa constant $\kappa = T.T_1 = 91(4)$ mK's obtained earlier at high $T$ in high $H_0$ /2/.

Our $\text{AuIn}_2$ samples was made from the same bulk material as used by Andres and Wernick /1/ and ground to a particle size of $\sim 20$ $\mu$m. The powder was not annealed. The field homogeneity over the sample volume was $\sim 5 \times 10^{-6}$. The measurements were done in the mixing chamber of a dilution cryostat.

"Bavarian Millimill" is a joint project of G. Eska, N. Kartascheff, J. Kraus, K. Neusailer, K. Uhlig, W. Wiedemann (ZTTP), W. Schoepe (Universität Regensburg) and F. Wolffle (Technische Universität München) It is supported by the Deutsche Forschungsgemeinschaft.
we attribute the longer $T_2$ to the Zeeman splitting and the shorter one mostly to strong quadrupole interaction caused by strains and imperfections in the sample. From ref. /1/ it is known that in bulk material quadrupole effects are negligible. Taking $T_2 = 44 \mu s$ we deduce a nuclear ordering temperature of 1.1 K for bulk AuIn$_2$.

Figure 2 shows some results of the $T_1$ measurements taken in a time interval $200 \mu s \leq t \leq 10 s$.

![Figure 2: Relaxation of the longitudinal magnetization to equilibrium after a $\pi$ pulse. Straight lines correspond to the Korringa constant of ref. /2/. The insert shows the early time behaviour in an expanded time scale. Similar results were found for $H_0 = 38.5\, mT$. The relaxation for short times after a $\pi$ tipping pulse is far off from the Korringa behaviour indicated by the straight lines corresponding to $\kappa = 91\, mK's/2$. The short-time relaxation rate is compiled in figure 3 for different $H_0$, tipping angles and bath temperatures. A striking feature of all these data is a universal power-law time dependence up to 0.5 s, although the temperatures of the conduction electrons are quite different due to different eddy current heating. The non-exponential relaxation is presumably caused by strain-induced quadrupole interaction which in addition leads to a wide distribution of energy levels and hence to an incomplete saturation of the spin system by the $\pi$ pulse. Since it is unknown how much all possible relaxation channels are contributing to the decay we consider the total rate as the sum of a time dependent part and the Korringa part in order to fit the data. The Korringa constant $\kappa$ was found to be $10^{-4} A$/s.

![Figure 3: Spin-Lattice relaxation rate vs. time for different experimental conditions. Dashed lines indicate the Korringa rate. Field dependent and we obtain 112(2) mK's at 74.3 mT and 82(5) mK's at 38.5 mT. Comparing AuIn$_2$ with Cu as nuclear refrigerant (assuming the same volume, heat leak and initial conditions $H_i/T_i$) we calculate the lowest possible electronic temperature $T_e^{\text{min}}$ (AuIn$_2$) to be a factor of 4 less than $T_e^{\text{min}}$ (Cu). With a heat leak of 30 pW/cm$^2$ the warm up time to $T_e^{\text{min}}$ (Cu) is $37.1/T_1$ seconds, i.e. in general some hours. Alternatively, stopping demagnetization at $T_e^{\text{min}}$ (Cu) the cooling power of AuIn$_2$ is larger by a factor of 5.8. This in conjunction with the 10 times shorter $T_1$ than that of Cu makes AuIn$_2$ a promising candidate for nuclear refrigeration.
