Abstract - Polycrystalline tetragonal zirconia materials (TZP) have been obtained by normal sintering from submicronic powders with low additions of Y$_2$O$_3$. Mechanical properties have been studied as a function of temperature, up to 900°C. Fracture toughness (about 10 MPa$\sqrt{m}$ at room temperature) decreases linearly from 200°C to 600°C. Results are discussed according to toughening mechanisms (phase transformation) on the basis of the microstructure and stability of the tetragonal phase.

I - INTRODUCTION

The application of phase transformations to enhance toughness of ceramic materials has been studied first in the case of partially stabilized zirconia (P.S.Z.). In these ceramics, the metastable phase is present as fine coherent precipitates in a large-grain cubic matrix /1,2/. These materials are usually made by sintering in the cubic/tetragonal field followed by controlled precipitation treatments, or in a single step process by sintering in the cubic/tetragonal field. In both cases, the microstructure is made up of large grains (cubic phase), and this is a limiting factor for mechanical properties. Furthermore, these properties are strongly dependent on thermal history of the material.

With an accurate control of grain size and additives content, single phase tetragonal zirconia materials (TZP) can be obtained /3/. In this type of material the toughening phase, i.e. the phase which leads to energy absorption by stress-induced transformation, is not restricted because all the material is in the tetragonal form: also, the toughening effect can be potentially maximized and the fracture toughness is considerably increased compared to all other P.S.Z..
Furthermore, the grain size is very fine (between 0.1 and 1 μm), and the fracture strength can also be considerably enhanced. Main results have been obtained with small Y₂O₃ additions (Y-TZP), and a dependence of mechanical behaviour on Y₂O₃ content has been observed /4/; the effect of raw powder characteristics and sintering conditions has also been reported /5,6/. Thus, it has been observed that Y-TZP fracture strength increases if the tetragonal grain size is reduced, whereas fracture toughness is maximized at the largest possible tetragonal grain size — for a given Y₂O₃ content —.

All high G_f and K_{IC} values of TZP reported are concerned with room temperature conditions. In this work, we have observed the mechanical properties temperature dependence of Y-TZP materials. The results are discussed in view of the theoretical predictions based on the variation of chemical free energy change /7/.

II - EXPERIMENTAL PROCEDURE

II-1 - Material

Materials studied are fine grained tetragonal zirconia with 5.2 wt % Y₂O₃ (~3 mole %). Two batches have been obtained (Y-TZP 1 and Y-TZP 2) by pressureless sintering (1500°C - 4 h) from mixed submicron powders. Only milling conditions have been modified from Y-TZP 1 to Y-TZP 2, to obtain finer microstructure. Densities are about 94 to 96.5% of theoretical density, and the mean grain size is between 0.65 and 0.8 μm.

Relative contents of tetragonal and monoclinic phases have been calculated by X-Ray diffraction from (111)m, (111)m and (111)t reflexion intensities /8/.

II-2 - Mechanical experiments

The fracture strength (G_f) and the fracture toughness (K_{IC}) values have been obtained with 3 points bending tests (15 mm span), at a cross-head speed of 0.1 mm/min. Specimens (4 x 3 x 22 mm³) were machined and polished (6 μm and 1 μm diamond paste) from sintered bodies. K_{IC} measurements have been performed on notched beams (S.E.N.B.) with a straight through notch of 1.6 mm depth (a/w = 0.4) and a tip radius of 80 μm. To eliminate induced residual stresses, annealing treatments at 950°C (15 min) have been made with all the specimens. Experiments were performed in air, up to 900°C, with a special high temperature testing apparatus /9/.

III - RESULTS

In the studied Y-TZP materials case, we did not observe any significant amount of cubic (c) phase. The tetragonal phase proportion is between 78% and 90% in as machined specimens and increases, in all specimens, to values higher than 95% after 950°C annealing.

Room temperature mechanical characteristics are similar to those reported for similar materials /4, 10, 11/. The high toughness values (~10 MPa V m) can be correlated to the contribution of a stress-induced phase transformation to the fracture energy. This mechanism is confirmed by a systematic analysis of the different crystallographic varieties: one observes a reduction of the tetragonal phase proportion from 95% (before fracture) to 65% on fracture faces /12/. According to the thermodynamic approach proposed by F.F. IANGE, the phase transformation toughening effect can be expressed as, /13/:

\[
K_c^2 - K_o^2 = \frac{2R E_c V_i (|\Delta G_c| - \Delta U_{SE} \cdot f)}{1 - \nu_c^2} \]  

(1)
Fig. 1 - Fracture strength temperature dependence of Y-TZP material

Fig. 2 - Influence of temperature on the fracture toughness of Y-TZP materials
With \( K_0 = 3 \) MPa \( \sqrt{\text{m}} \) (toughness of material without any transformation toughening phenomenon), \( V_i = 95\% \) (volume fraction of retained tetragonal phase), \( E_c = 180 \) GPa, \( \gamma_c = 0.25 \) and \( R = 0.8 \) \( \mu \text{m} \) (size of the transformation zone associated with the crack), one obtains (for \( K_c = 9.2 \) MPa \( \sqrt{\text{m}} \)): \( \Delta G_c - f \Delta U_{\text{se}} = 258 \) M\( \text{J}.\text{m}^{-3} \). This value expresses the work done, per unit volume, by the stress field to induce the transformation. Microstructure observations of TZP materials reveal the presence of twinning in transformed (monoclinic) grains and of microcracks along grain boundaries /13/. This point contributes to relieving strain energy during fracture and so increases the term \( \Delta G_c - f \Delta U_{\text{se}} \) in equation (1): this can explain the high toughness values we observed. However, the fracture strength values (Y-TZP 1 and Y-TZP 2) are quite low if compared to other T.Z.P.: this is due to the presence of important residual porosity (\( d = 95\% \) \( \text{dth} \)) and also the presence of large inclusions (from raw powder and milling media). According to these observations, processing has been slightly modified and one observes, on new TZP batches (K), fracture strength values of about 1000 MPa.

The influence of temperature on mechanical properties is illustrated in fig. 1 and fig. 2. The fracture toughness decreases quite linearly between 200\( ^\circ \)C and 600\( ^\circ \)C, and is similar to that of stabilized zirconia at 800\( ^\circ \)C. The fracture strength variation is similar, except an important decrease at about 200\( ^\circ \)C. This low temperature degradation can be correlated to an activated formation of monoclinic phase on the specimens surface. Such a behaviour has been reported by different authors, and seems to reach a maximum at 200\( ^\circ \)C /14/. The decrease of \( K_c \) with temperature is similar to the chemical free energy change (\( \Delta G_c \)) temperature dependence: for the tetragonal \( \longrightarrow \) monoclinic transformation, \( |\Delta G_c| \) decreases with increasing temperature.

Fig. 3 - Work (per unit volume) to induce the transformation versus temperature

The critical temperature \( T_0 \), i.e. the temperature corresponding to the value \( (\Delta G_c - f \Delta U_{\text{se}}) = 0 \), is defined in our materials at about 625\( ^\circ \)C: there is no more toughening effect at higher temperatures and \( K_c = K_0 \) (equ. (1)). We have plotted

(*) ZFYT grade : DESMARQUEST CERAMIQUE TECHNIQUE - 27025 ENREUX (France)
calculated values of $(\Delta G_C - f \Delta U_{se})$ versus temperature in Fig. 3; some results reported by Lange have also been plotted in Fig. 3 /7/. However, because $\Delta G_C$ is the greatest temperature dependence factor in Eqn. (1), the slope must be nearly the same as $d[\Delta G_C]/dT$ for pure ZrO$_2$ /15/. Recalculated values of $(\Delta G_C - \Delta U_{se} f)$ with $R=1.38 \mu m$ give a resulting slope in good agreement with reported thermodynamic data ($0.248 \text{ MJ.m}^{-3}. \text{ C}^{-1}$), and the new value of $\Delta G_C$ at room temperature is about 150 MJ.m$^{-3}$. This new value is slightly lower than the calculated value for hot-pressed Y-TZP with 2 mole% Y$_2$O$_3$ (188 MJ.m$^{-3}$) /7/. This is consistent with the effect of alloy content: $\Delta G_C$ decreases with increasing Y$_2$O$_3$.

IV - CONCLUSION

High toughness values (10 MPa $\sqrt{m}$) have been obtained in pressureless sintered tetragonal zirconia materials (Y-TZP). The toughening effect can be explained by the contribution of a stress-induced phase transformation.

In the materials studied, the critical temperature is 625°C. The energy change at room temperature associated with the transformation is about 150 MJ.m$^{-3}$, with a transformation zone size of 1.38 $\mu$m. Results are consistent with thermodynamic data.
