Résumé. — Nous examinons des fluctuations dans un cristal liquide nématique autour d'un état stationnaire de non-équilibre résultant d'un mouvement de cisaillement. Dans le cas particulier d'un vecteur d'onde situé dans le plan de cisaillement nous trouvons que le pic central du spectre de diffusion de la lumière (dû aux fluctuations du directeur), est élargi et aplati (en plus d'un déplacement Doppler trivial) et qu'il est réduit en intensité totale par comparaison avec l'état d'équilibre. Pour l'essentiel, les contributions de non-équilibre ne sont pas sensibles au vecteur d'onde puisque le mouvement de cisaillement rompt de l'extérieur une symétrie déjà spontanément brisée dans des nématiques.

Abstract. — We theoretically investigate fluctuations in a nematic liquid crystal about a non-equilibrium steady state due to a stationary shear flow. For the special case, where the wave-vector lies in the shear plane, we find that the central peak in the light scattering spectrum (caused by director fluctuations) is (in addition to the trivial Doppler shift) considerably flattened, broadened and reduced in total intensity, if compared to the equilibrium situation. The non-equilibrium contributions are essentially wave-vector independent, because the shear flow breaks just that symmetry (externally), which is already broken spontaneously in nematics.

1. Introduction and results. — During the last several years there has been considerable interest in the study of light scattering in non-equilibrium (but near equilibrium) situations (Refs. [1-4] and references cited therein). All these studies focussed on the effects of fluctuations of simple fluids in non-equilibrium situations like e.g. static temperature gradient or stationary shear flow. Parts of the results of the theoretical papers were verified experimentally [5].

In a recent paper by the present authors [6] the influence of a static temperature gradient on the light scattering spectrum in nematic liquid crystals was investigated. The central peak caused by director fluctuations was found to be deformed into an asymmetric shape (and slightly shifted).
Thereby the non-equilibrium contributions are wave-vector dependent and are measurable only by small angle scattering.

In the present paper we investigate the fluctuation spectrum in nematics when the non-equilibrium situation is due to a stationary shear flow. This is the unique case where the external force breaks just that symmetry, which is already spontaneously broken. That means, the director $\mathbf{n}$ of the nematic phase takes a certain direction in the shear plane (given by the flow alignment angle [7]) and fluctuations of $\mathbf{n}$ experience a restoring force, which does not vanish in the long wave length limit $k \to 0$. These are the fluctuations which give the non-equilibrium contributions to the central peak (caused by director fluctuations) in the light scattering spectrum of nematics. We find the equilibrium Lorentzian to be Doppler shifted, flattened, broadened in a symmetric but non-Lorentzian manner, and reduced in total intensity because of the non-equilibrium situation. This reduction of total intensity stems from an increase of the elastic energy due to the external shear flow. The effects are large, roughly in the range of 10 \%, and should, therefore be experimentally detectable.

Our results are obtained by the following procedure: the nonlinear hydrodynamic equations (including Langevin forces) are linearized about the non-equilibrium steady state. A fluctuation-dissipation theorem is employed relating correlation functions of Langevin forces to hydrodynamic transport parameters. This relation is the same as in the case of true equilibrium, while the non-equilibrium situation is manifest in the linearized hydrodynamic equations, only (Section 2).

In order to be concise, we restrict ourselves to the special case, where the wave vector lies in the shear plane. Director fluctuations normal to the shear plane then couple only to the appropriate component of linear momentum and correlation functions of the former can easily be extracted from the linearized hydrodynamic equations (Section 3).

Implications for the light scattering spectrum are discussed subsequently.

2. Hydrodynamic equations. — We consider a nematic layer of thickness $d$ subject to a stationary shear flow. The geometry is sketched in figure 1. In the steady state the director $\mathbf{n}^0 = \hat{e}_y \cos \theta_0 + \hat{e}_z \sin \theta_0$ lies in the $y$-$z$-plane enclosing an angle $\theta_0$ (1) with the $y$-axis and the velocity field is given by

$$\mathbf{v} = \left( S_0 \frac{d}{2} + S_1 z \right) \hat{e}_x. \quad (2.1)$$

This form contains e.g. the special case i) upper plate moving with velocity $v$ and lower plate fixed for $S_0 = S_1 = v/d$ and ii) upper and lower plate moving with velocity $v$ and $-v$, respectively for $S_0 = 0$ and $S_1 = v/d$.

![Fig. 1. — Scheme of the experimental set up: one or both plates are moved in $y$ and/or in $-y$-direction. The director field $\mathbf{n}^0$ encloses an angle $\theta_0$ with the velocity field $\mathbf{v}$. All calculations are done for a layer infinitely extended in the $x$- and $y$-direction.]

(1) This flow alignment angle $\theta_0$ can be expressed by the hydrodynamic flow parameter $\lambda$ [7]: $\cos 2 \theta_0 = \lambda^{-1}$. 
In addition to equation (2.1) we have
\[
T = T_0, \quad p = p_0, \quad \rho = \rho_0, \quad g_x = g_z = 0, \quad g_y = \rho_0 v_y, \quad \phi_{ij} = 0
\] (2.2)
where \( p \) is the pressure, \( \rho \) the density, \( T \) the temperature, \( g_i \) the density of linear momentum, and \( \phi_{ij} \) is the thermodynamic conjugate of \( \nabla_i \rho_j \). [8, 9]
The equations of state are [8, 9]
\[
\begin{align*}
\rho_i &= \rho v_i \\
\delta \rho &= \chi E \delta p + \alpha \delta T \\
\phi_{ij} &= K_{ijkl} \nabla_j \rho_k.
\end{align*}
\] (2.3)
In appendix I we derive from the general nonlinear hydrodynamic equations (1.1)-(1.3) including fluctuating forces [10] the equations linearized about the non-equilibrium steady state (1.4) and (1.5). As it is easily checked, \( \delta n_x \) and \( g_x \) decouple from all other variables in the special case \( k_x = 0 \) (i.e. \( k \) lies in the shear plane). This simplifies the resulting formulas considerably and we, therefore, restrict ourselves to this case in the following.
Using the notations
\[
\begin{align*}
\nabla_{||} &= \hat{n}^0 \cdot \nabla = \nabla_x \cos \theta_0 + \nabla_z \sin \theta_0 \\
\nabla_{\perp} &= \hat{e}_x \times (\nabla \times \hat{n}^0) = \nabla_x \sin \theta_0 - \nabla_z \cos \theta_0
\end{align*}
\] (2.4)
we obtain from (1.4) and (1.5) the linearized equations for \( \delta n_x \) and \( g_x \) in the case \( k_x = 0 \)
\[
\begin{align*}
\delta \dot{n}_x + \left( S_0 \frac{d}{z} + S_1 \frac{d}{z} \right) \nabla_{\perp} \rho_x - \frac{1}{2}(\lambda + 1) \nabla_{||} v_x - \xi(K_2 \nabla_{\perp}^2 + K_3 \nabla_{||}^2) n_x + \\
&+ S_1 \lambda \cos \theta_0 \sin \theta_0 \delta n_x = \pi x
\end{align*}
\] (2.5)
and
\[
\begin{align*}
\hat{v}_x + \left( S_0 \frac{d}{z} + S_1 \frac{d}{z} \right) \nabla_{||} v_x + \frac{1}{2\rho_0}(\lambda + 1) \nabla_{||}(K_2 \nabla_{\perp}^2 + K_3 \nabla_{||}^2) n_x - \frac{1}{\rho_0}(v_3 \nabla_{\perp}^2 + v_2 \nabla_{||}^2) v_x + \\
&+ \frac{1}{\rho_0} S_1(2[v_1 - v_3] \sin \theta_0 \cos \theta_0 \nabla_{||} + [v_3 - v_2] \sin \theta_0 \cos \theta_0 \nabla_{\perp}) n_x = \nabla_j \sigma_{xj}.
\end{align*}
\] (2.6)
In equation (2.6) we have assumed incompressibility i.e. \( v_2 = v_4 \) and \( v_5 = 0 \). For the general case [9]. Equations (2.5) and (2.6) differ from the hydrodynamic equations linearized about the equilibrium state by the occurrence of the \( S_0 \) and \( S_1 \)-terms. \( \pi_x \) and \( \sigma_{xj} \) are fluctuating forces [10] required to ensure the self-consistency of the hydrodynamic equations. They are assumed to be Gaussian and Markoffian, i.e. \( f_\xi \in \{ \sigma_{xj}, \pi_x \} \)
\[
\langle f_\xi(1) f_\zeta(2) \rangle = k_B(\gamma_{\xi\zeta} + \gamma_{\zeta\xi}) \delta(1 - 2).
\] (2.7)
Restricting ourselves to situations near equilibrium, (i.e. well below any threshold of a shear flow instability [11-16]) the fluctuation dissipation theorem holds and the entropy production serves as a potential [3, 17]. The coefficients \( \gamma_{\xi\zeta} \) in equation (2.7) are then given by the dissipative transport parameters of the appropriate hydrodynamic equations and equation (2.7) reads explicitly
\[
\begin{align*}
\langle \sigma_x(r_1 t_1) \sigma_x(r_2 t_2) \rangle &= 2 k_B T \nu_{xjkl} \delta(r_1 - r_2) \delta(t_1 - t_2) \\
\langle \pi_x(r_1 t_1) \pi_x(r_2 t_2) \rangle &= 2 k_B T \xi \delta(r_1 - r_2) \delta(t_1 - t_2)
\end{align*}
\] (2.8)
Equations (2.8) are the same as in equilibrium and well known in literature [10]. The terms proportional to $S_0$ in equations (2.5) and (2.6) can be treated exactly. They simply describe a Doppler shift, and they can be eliminated by a Galilean transformation to a proper moving frame. The $S_1$-terms reflect the non-equilibrium situation. Since their influence is expected to be rather small we will treat them perturbatively, i.e. we will only consider linear order in $S_1$. In appendix II it is shown that in this order the non-autonomous contributions proportional to $S_1 z$ (in the drift terms) do not contribute to the correlation function of $\delta n_x$ and can, therefore, be dropped from equations (2.5) and (2.6) for our purposes (2).

We can now Fourier transform equations (2.5) and (2.6) and obtain the final equations

$$
\left( i\omega + S_0 \frac{d}{2} ik_x + \tilde{\mu}^2 \right) v_x(k\omega) - \left( \frac{x+1}{2\rho_0} ik_\parallel \tilde{K}^2 + i\tilde{S}_1 \right) \delta n_x(k\omega) = \frac{i}{\rho_0} \left( k_\perp \sigma_{x\perp} + k_\parallel \sigma_{x\parallel} \right) \tag{2.9}
$$

where we have introduced the transverse relaxation time

$$
\Gamma^{-1} = (2 S_1 \lambda \cos \theta_0 \sin \theta_0)^{-1} = S_1^{-1} \cotan 2 \theta_0
$$

and the abbreviations

$$
\tilde{\mu}^2 = \frac{1}{\rho_0} (v_3 k_\parallel^2 + v_2 k_\perp^2) \equiv \mu_3 k_\parallel^2 + \mu_2 k_\perp^2
$$

$$
\tilde{K}^2 = K_2 k_\perp^2 + K_3 k_\parallel^2
$$

$$
\tilde{\sigma} = 2(\mu_1 - \mu_3) \sin \theta_0 \cos \theta_0 k_\parallel + (\mu_3 - \mu_2)(\sin^2 \theta_0 - \cos^2 \theta_0) k_\perp.
$$

3. Correlation functions and light scattering. — For the correlation function (3) $\chi^{\omega}_{n_x n_x}(k)$ we obtain from equations (2.8) and (2.9)

$$
\chi^{\omega}_{n_x n_x}(k) = 2 k_B T_0 \frac{\xi(\Omega^2 + \tilde{\mu}^2 \hat{\mu}^2) + \frac{\lambda^2}{\xi^2} k_\parallel^2 \tilde{\mu}^2}{(\Omega^2 + \frac{\lambda^2}{\xi^2} k_\parallel^2 + \Xi^2) (\hat{\mu}^2 + \frac{\lambda^2}{\xi^2} k_\parallel^2)^2} \tag{3.1}
$$

where

$$
\Omega = \omega + \frac{1}{2} S_0 \frac{d}{2} \sin \theta_0
$$

$$
\xi^2 = \xi \tilde{K}^2 + \frac{1}{\Gamma}
$$

$$
\lambda^2 = \frac{\lambda}{\xi^2} k_\parallel^2 \tilde{K}^2 + \frac{1}{\Gamma} (\lambda + 1) \frac{1}{\rho_0} k_\parallel \tilde{S}_1
$$

$$
(2) \text{A similar situation arises for the density correlation function in simple fluids [3].}
$$

$$
(3) \text{The definition is}
$$

$$
\langle \delta n_x(k\omega) \delta n_x^*(k' \omega') \rangle \equiv \chi^{\omega}_{n_x n_x}(k) \delta(\omega - \omega') \delta(k - k').
$$

$$
\langle \delta n_x(k\omega) \delta n_x^*(k' \omega') \rangle \equiv \chi^{\omega}_{n_x n_x}(k) \delta(\omega - \omega') \delta(k - k').
$$
where
\[ M = \frac{\tilde{\xi} \mu^2 \tilde{\xi}^2 + \lambda_2^2 k_{\parallel}^2 \tilde{\mu}^2 - \xi \Omega_1^2}{\Omega_2^2 - \Omega_1^2} \]
\[ P = \frac{\tilde{\xi} \Omega_2^2 - \xi \tilde{\xi}^2 \mu^2 - \lambda_1^2 k_{\parallel}^2 \tilde{\mu}^2}{\Omega_2^2 - \Omega_1^2} \] (3.4)

and
\[ \Omega_{1,2} = \frac{i}{2} (\tilde{\mu}^2 + \tilde{\xi}^2) \pm \frac{1}{2} [(\tilde{\mu}^2 + \tilde{\xi}^2)^2 + 4 \lambda^4 + 4 \tilde{\mu}^2 \tilde{\xi}^2]^{1/2}. \] (3.5)

The equilibrium part of $\chi_{\omega}^{\alpha,\omega}(\mathbf{k})$ is obtained from (3.3)-(3.5) if one puts $S_0 = 0 = S_1$, i.e. $\Omega = \omega$, $\tilde{\xi}^2 = \xi \tilde{K}^2$ and $\lambda^4 = \lambda^2 k_{\parallel}^2 \tilde{K}^2$, there.

The correlation function $\chi_{\omega}^{\alpha,\omega}(\mathbf{k})$ is measured by inelastic, depolarized light scattering [8, 9]. In our case the polarization of the electric vector changes from the direction parallel to $\hat{n}$ to the $x$-direction and $\omega$ and $\mathbf{k}$ are the differences between incoming and scattered frequencies and wave vectors, respectively.

Concentrating on the narrow and high peak in (3.3), which is responsible for the high scattering intensity in nematic liquid crystals, equation (3.3) simplifies into
\[ \chi_{\omega}^{\alpha,\omega}(\mathbf{k}) = 2 k_B T_0 P(\Omega^2 + \Omega^2_2)^{-1}. \] (3.6)

Assuming the inequality $\tilde{\mu}^2 \gg \tilde{\xi} \tilde{K}^2$ to hold, which implies also $\tilde{\mu}^2 \gg \tilde{\xi}^2$ and $\tilde{\mu}^2 \gg \lambda^4$ for all realistic values of $S_1$, the equilibrium part of $\chi_{\omega}^{\alpha,\omega}(\mathbf{k})$ reads (cf. also [9])
\[ \chi_{\omega}^{\alpha,\omega,eq}(\mathbf{k}) = \frac{2 k_B T_0}{\tilde{K}^2} \frac{\omega_{1/2}^2}{\Omega^2 + \omega_{1/2}^2} \] (3.7)

with
\[ \omega_{1/2} = \tilde{\xi} \tilde{K}^2 + \tilde{\lambda}^2 k_{\parallel}^2 \tilde{K}^2 / \tilde{\mu}^2 \]

where we have already accounted for a Doppler shift $\Omega \neq \omega$ (for $S_0 \neq 0$).

Up to linear order in $S_1$ the non-equilibrium part of
\[ \chi_{\omega}^{\alpha,\omega}(\mathbf{k}), \quad \delta \chi_{\omega}^{\alpha,\omega}(\mathbf{k}) \equiv \chi_{\omega}^{\alpha,\omega}(\mathbf{k}) - \chi_{\omega}^{\alpha,\omega,eq}(\mathbf{k}), \]

is given by
\[ \delta \chi_{\omega}^{\alpha,\omega}(\mathbf{k}) = - \tilde{S}_1 \frac{\omega_{1/2}}{\Omega^2 + \omega_{1/2}^2} \chi_{\omega}^{\alpha,\omega,eq} \] (3.8)

with
\[ \tilde{S}_1 = \gamma + (\lambda + 1) \tilde{S}_1 k_{\parallel} / \tilde{\mu}^2 \]
\[ = 2 \lambda S_1 \cos \theta_0 \sin \theta_0 + (\lambda + 1) S_1 [(\mu_1 - \mu_3) \sin 2 \theta_0 k_{\parallel}^2 + [\mu_2 - \mu_3] \cos 2 \theta_0 k_{\parallel} k_{\perp}] \times \]
\[ \times (\mu_3 k_{\parallel}^2 + \mu_2 k_{\perp}^2)^{-1} \]
\[ = S_1 \tan 2 \theta_0 + S_1 (1 + \cos 2 \theta_0) [(\mu_1 - \mu_3) \tan 2 \theta_0 k_{\parallel}^2 + [\mu_2 - \mu_3] k_{\parallel} k_{\perp}] \times \]
\[ \times (\mu_3 k_{\parallel}^2 + \mu_2 k_{\perp}^2)^{-1} \] (3.9)

where $\omega_{1/2}$ and $\chi_{eq}$ are defined by (3.7). Thus, we have found that the (Doppler shifted) equilibrium Lorentzian is reduced in height by
\[ \frac{| \delta \chi(\Omega = 0) |}{\chi_{eq}(\Omega = 0)} = \frac{\tilde{S}_1}{\omega_{1/2}} \equiv a \] (3.10)
and symmetrically broadened into a non-Lorentzian shape (Fig. 2). The relative increase in half-width is (up to linear order in \( S_1 \))

\[
\frac{\Omega(\chi_{\text{eq}}) = \frac{1}{2} \chi_{\text{max}}^{\text{eq}}) - \Omega(\chi_{\text{eq}} = \frac{1}{2} \chi_{\text{max}}^{\text{eq}}) \approx \frac{1}{2} \frac{S_1}{\omega_{1/2}} = \frac{a}{2} \cdot \omega_{1/2}
\]

(3.11)

Fig. 2. — The central light-scattering peak (caused by transverse director fluctuations) in equilibrium \( \chi^{eq} \) and non-equilibrium \( \chi = \chi^{eq} + \delta\chi \) according to equations (3.8) and (3.7) for typical values given in the text. \( \omega_{1/2}^{\text{eq}} \) and \( \omega_{1/2} \) are the frequencies, where the equilibrium and non-equilibrium peak take half of their maximal value, respectively.

As already discussed in the introduction, neither \( \delta\chi \) nor \( S_1 \) vanish in the limit \( k_{||} \to 0 \) (or \( k_{\perp} \to 0 \)) and \( S_1 \) depends only very weak on the direction of \( k \). There, we have also pointed out the differences to the case of an external static temperature gradient [6].

Besides the above mentioned change in height and shape of the equilibrium peak, there is a reduction in overall intensity due to the non-equilibrium situation. For the static correlation function

\[
\chi^{\text{stat}}_{n_n,n_n}(k) \equiv \frac{1}{2\pi} \int_{-\infty}^{\infty} \chi^{\text{eq}}_{n_n,n_n}(k) \, d\omega
\]

we obtain from (3.6)

\[
\chi^{\text{stat}}_{n_n,n_n}(k) \approx \frac{k_B T_0}{K^2} \frac{\omega_{1/2}^{\text{eff}}}{\omega_{1/2} + S_1} \approx \chi^{\text{stat}}_{n_n,n_n,\text{eq}}(k)(1 - a).
\]

(3.12)

This means that the elastic energy of the director fluctuations (i.e. the gradient energy) is raised and described by « effective static susceptibilities » \( K_{2,3}^{\text{eff}} = K_{2,3}(1 + a) \). This stabilization of the director field by the shear flow reduces the scattering intensity. Such an effect on the intensity is not present in the case of an external temperature gradient [6]. In order to get an estimate for the importance of the non-equilibrium effects we insert typical values (\( k \approx 10^3 \) cm\(^{-1}\), \( \xi = 10 \) cm s\(^{-1}\), \( K \approx 10^{-6} \) g cm s\(^{-2}\), \( \mu \approx 10^{-1} \) cm\(^2\) s\(^{-1}\), \( \tan 2 \theta_0 \approx 1 \), \( (\mu_1 - \mu_3)/\mu_3 \approx (\mu_2 - \mu_3)/\mu_2 \approx 10^{-1} \), \( S_1 \approx 1 \) s\(^{-1}\), \( v \approx 1 \) cm s\(^{-1}\), \( d = 1 \) cm) and obtain \( a \approx 10 \% \), which
LIGHT SCATTERING IN SHEARED NEMATICS

brings all above mentioned effects into the experimentally detectable range. For \( S_0 = S_1 \) the Doppler shift is then 500 Hz. The non-equilibrium effects on the light scattering spectrum predicted above are much bigger than any other non-equilibrium effects in other systems reported so far. The reasons are that in the present case i) the external force breaks just that symmetry which is spontaneously broken by the system and ii) fluctuations of that variable, which describes that broken symmetry, are the main sources for light scattering.

Appendix I. — For the nonlinear hydrodynamic equations of a nematic liquid crystal we have [8, 18]

\[
\dot{\rho} + \nabla_i \dot{g}_i = 0 \tag{I.1}
\]

\[
\dot{g}_i + \nabla_k v_k g_i + \nabla_i p + \frac{1}{2} \lambda \nabla_j (n_i \phi_{jl} + n_j \phi_{il}) + \frac{1}{2} \nabla_j (\phi_{kl} \nabla_k n_l + \phi_{kl} \nabla_l n_k) - \frac{1}{2} \nabla_j \nabla_k (n_i \phi_{jk} - n_j \phi_{ik}) = \nabla_j v_{ijkl} \nabla_k v_i \tag{I.2}
\]

\[
\dot{n}_i + v_k \nabla_k n_i - \frac{1}{2} \lambda (\delta_{ii} - n_i n_j) n_k (\nabla_i v_k + \nabla_k v_i) + \frac{1}{2} (\delta_{ii} - n_i n_j) n_k (\nabla_i v_k - \nabla_k v_i) = \xi \nabla_j \phi_{ij} \tag{I.3}
\]

Linearizing equations (I.1)-(I.3) around the stationary state (2.1), (2.2), characterized by superscript zero, yields

\[
\delta \dot{\rho} + v_i^0 \nabla_i \rho + \rho_0 \nabla_i v_i = 0
\]

\[
\rho_0 \dot{v}_i + v_k^0 \rho_0 \nabla_k v_i + \nabla_i p + \frac{1}{2} \lambda (n_i^0 \nabla_i \phi_{jl} + n_j^0 \nabla_i \phi_{il}) - \frac{1}{2} (n_i^0 \nabla_j \phi_{jk} - n_j^0 \nabla_j \phi_{ik}) = \nabla_j \phi_{ijkl} \nabla_k v_i \tag{I.4}
\]

\[
\delta \dot{n}_i + v_k^0 \nabla_k \delta n_i + \frac{1}{2} \lambda (n_i^0 \delta n_i + n_i^0 \delta n_j) n_k^0 (\nabla_i v_k^0 + \nabla_k v_i^0) + \frac{1}{2} (n_i^0 \delta n_i + n_i^0 \delta n_j) n_k^0 (\nabla_i v_k^0 - \nabla_k v_i^0) - \frac{1}{2} (\delta_{ii} - n_i^0 n_j^0) \delta n_k (\nabla_i v_k^0 + \nabla_k v_i^0) + \frac{1}{2} (\delta_{ii} - n_i^0 n_j^0) \delta n_k (\nabla_i v_k^0 - \nabla_k v_i^0) - \frac{1}{2} (\delta_{ii} - n_i^0 n_j^0) n_k^0 (\nabla_i v_k - \nabla_k v_i) + \frac{1}{2} (\delta_{ii} - n_i^0 n_j^0) n_k^0 (\nabla_i v_k - \nabla_k v_i) = \xi \nabla_j \phi_{ij}
\]

In equation (I.4) the expressions \( \phi_{ij} \) and \( v_{ijkl} \) are to be specified (cf. e.g. [8]). However, we need only \( \nabla_j \phi_{xlj} \) and \( v_{ijkl} \nabla_j \nabla_k v_i \) (cf. equation (2.1)) which are given by

\[
\nabla_j \phi_{xlj} = K_2 \varepsilon_{xjl} n_p^0 \varepsilon_{klq} n_o^0 \nabla_j \nabla_k n_l + K_3 n_j^0 n_k^0 \nabla_j \nabla_l n_x
\]

\[
\nabla_j v_{xylj} = (v_3 - v_2) (n_j^0 \nabla_x n_z + n_z^0 \nabla_x n_j) + 2(v_1 + v_2 - 2 v_3) n_j^0 n_k^0 n_o^0 \nabla_j \nabla_k n_x \tag{I.5}
\]

In (I.5) we have assumed incompressibility, i.e. \( v_4 = v_2 \) and \( v_5 = 0 \) for simplicity. The general case \( v_4 \neq v_2, v_5 \neq 0 \) can easily be obtained from [8]. For the special case \( k_x = 0 \) and \( n^0 = \tilde{e}_x \cos \theta_0 + \tilde{e}_z \sin \theta_0 \) equations (2.5) and (2.6) follow from (I.5).
Appendix II. — In this appendix we will show that the $S_1 z$-terms of equations (2.5) and (2.6) do not contribute to $\langle n_k(k_\omega) n^*_k(k_\omega) \rangle$ in linear order. We replace $z$ by $q^{-1} \sin q z$ with $q z \ll 1$ and $q = q \hat{e}_z$. Fourier transforming equations (2.5) and (2.6) yields

$$
\left( i\omega + \frac{i}{2} S_0 dk_y + \xi_k^2 + \frac{1}{2} \Gamma \right) n_k - \frac{i}{2} (\lambda + 1) k_\parallel v_k - \pi_k = - \frac{S_1 k_y}{2 q} (n_{k-q} - n_{k+q})
$$

$$
\left( i\omega + \frac{i}{2} S_0 dk_y + \mu_k^2 \right) v_k - \left( \frac{i}{2 \rho_0} [\lambda + 1] k_\parallel \xi_k^2 + i\hat{u}_k S_1 \right) n_k - \frac{i}{\rho_0} k . \sigma_k = \frac{S_1 k_y}{2 q} (v_{k-q} - v_{k+q}).
$$

(II.1)

Throughout this appendix we suppress the index $x$ on $n_x, v_x, \pi_x$ or $\sigma_{xi}$; therefore, $n_{k-q}$ is a short hand notation for $n_x(k_\parallel - q \sin \theta_0, k_\perp + q \cos \theta_0, \omega)$ etc. In zeroth order, i.e. omitting the r.h.s. of equations (II.1), one can solve this inhomogeneous system of equations obtaining

$$
n_k^0 = A_k \pi_k + B_k \sigma_k \cdot k \\
v_k^0 = C_k \sigma_k \cdot k + D_k \pi_k
$$

(II.2)

where the specific form of $A_k \ldots D_k$ is not needed here. Inserting the zero-order-solution (II.2) into the r.h.s. of (II.1) leads to the first order result

$$
n_k^1 = A_k [\pi_k - \delta \pi_{k-q} + \delta \pi_{k+q}] + B_k [k . \sigma_k + \delta \sigma_{k-q} - \delta \sigma_{k+q}]
$$

(II.3)

with

$$
\delta \pi_{k\pm q} = \frac{S_1 k_y}{2 q} [A_{k\pm q} \pi_{k\pm q} + B_{k\pm q} \sigma_{k\pm q} (k \pm q)]
$$

$$
\delta \sigma_{k\pm q} = \frac{i S_1 k_y \rho_0}{2 q} [C_{k\pm q} \sigma_{k\pm q} (k \pm q) + D_{k\pm q} \pi_{k\pm q}].
$$

The required correlation function is given in first order by

$$
\langle n^*_k n_k^* \rangle - \langle n_k^0 n_k^{0*} \rangle = - |A_k|^2 \langle \pi_k \delta \pi^* + \pi^*_k \delta \pi \rangle \\
- B_k A_k^* \langle \delta \sigma \pi_k^* + k \cdot \sigma_k^* \delta \pi \rangle \\
- B_k^* A_k \langle \delta \sigma^* \pi_k + k \cdot \sigma_k \delta \sigma \rangle \\
- |B_k|^2 \langle k \cdot \sigma_k \delta \sigma^* + k \cdot \sigma_k^* \delta \sigma \rangle.
$$

(II.4)

However, the r.h.s. of (II.4) vanishes identically, since $\delta \sigma$ and $\delta \pi$ contain only fluctuating forces at wave vectors $k \pm q$, while $\pi_k$ and $\pi_k$ are at wave vectors $k$ and $\langle \pi_k \pi_k^* \rangle = \langle \pi_k \sigma_k \rangle = \langle \sigma_k \sigma_k^* \rangle = 0$ for $k \neq k'$ according to (2.8). Therefore, in first order, $\langle n_k n_k^* \rangle$ is the same, as we had omitted the $S_1 z$-terms from the beginning.
