HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
Abstract: We have studied the martensitic transformation and the order-disorder transitions in two families of composition related Cu-Al-Mn crystals. X-ray diffraction and calorimetric measurements have been performed to characterize order-disorder transitions. The entropy change at the martensitic transition has been computed from calorimetric measurements. Results show that its magnitude depends only on the martensite structure which, in turn, depends on the electronic concentration e/a. We have obtained $\Delta S = 1.51 \pm 0.05 \text{ J mol}^{-1} \text{ K}^{-1}$ for a transition to a 2H phase and $\Delta S = 1.26 \pm 0.06 \text{ J mol}^{-1} \text{ K}^{-1}$ for a transition to a 18R structure. We discuss the possibility of a magnetic contribution to $\Delta S$. Finally it is found that quenching has a marked influence on the martensitic transition temperature, but it does not affect the entropy change.

1. INTRODUCTION

The stability of the bcc phase exhibited at high temperature by numerous metals and alloys stems from the excess of vibrational entropy of this phase in relation to the close-packed structures that would be the stable phases from purely energetic considerations [1]. At low temperature, when the entropic term in the free energy is compensated by the energetic one, most of these systems undergo a martensitic transition to a close-packed structure [2]. Among the different systems undergoing a martensitic transition, a technologically interesting family is the one formed by Cu-based alloys. They belong to the Hume-Rothery class of materials for which the phase stability is dominated by the average number of valence electrons per atom ratio (e/a) [3]. In this family, commonly the bcc phase is only stable at high temperature but it can be retained at low temperature by means of a suitable cooling. For certain compositions this metastable bcc phase undergoes a martensitic transition. In addition, during cooling, these systems get configurationally ordered, and the degree of order achieved by the samples depends on the cooling rate; this is an important result since ordering can modify the relative stability between bcc and martensitic phases [4].

In this work we study the Cu-Al-Mn alloy system. In many respects, this alloy behaves very similarly to standard Cu-based alloys like Cu-Zn-Al or Cu-Al-Ni, but a significant difference is that Cu-Al-Mn is paramagnetic while other Cu-based alloys are diamagnetic. Hence, short range magnetic order could have an influence on the phase stability of Cu-Al-Mn. We have first characterized the (metastable) phase diagram and we have measured entropy changes during martensitic transition in two families of composition related Cu-Al-Mn crystals. Finally we have also analyzed the influence of quenches from above and below the ordering temperatures on the martensitic transition.
Table 1: Composition, e/a, martensitic transition temperature \( (M_s) \), latent heat (on cooling, \( L_c \), and on heating, \( L_h \)) and entropy change \( (\Delta S) \) of the different alloys investigated. The first set of alloys belongs to the \( \text{Cu}_3\text{Al}-\text{Mn} \) line and the second one to the \( \text{Cu}_3\text{Al}-\text{Cu}_3\text{Mn}_2 \) line.

2. EXPERIMENTAL

Samples belonging to the two composition related alloy families, \((\text{Cu}_{0.75}\text{Al}_{0.25})_1-x\text{Mn}_x\) \((0 \leq x \leq 0.09)\) and \((\text{Cu}_3\text{Al})_{1-x}\text{Mn}_{2x}\) \((0 \leq x \leq 0.22)\), have been used in the experiments. Their specific compositions are given in table 1. Polycrystalline cylindrical shaped ingots \( (5 \text{ mm diameter}) \) were obtained by melting pure elements \( \text{purity 99.99\%} \). From them, slices \( (2 \text{ mm thick}) \) have been cut using a low speed diamond saw. The damaged surface has been etched away in a 40 \% HNO\(_3\) solution.

Calorimetric measurements between 100 K and room temperature have been performed using a microcalorimeter specifically designed to investigate solid-solid phase transitions \( \text{details of this instrument can be found in [5]} \). A differential scanning calorimeter from TA Instruments has been used for the range 300-850 K and, for temperatures above 850 K, phase transitions have been detected using a high temperature differential thermal analysis cell. In all cases, the studied sample has been first heat treated for 900 s at 1080 K, air cooled to a temperature \( T_s \) and quenched in a mixture of ice and water. The reference heat treatment consisted of a direct quench from 1080 K followed by a three-day room temperature ageing.

3. RESULTS

3.1 Phase Diagram

In this section we present the \( \text{metastable} \) phase diagram corresponding to the two studied composition lines. Results have been obtained with samples that have followed a reference heat treatment. The order-disorder transitions have been characterized by means of x-ray diffraction and calorimetric measurements. Except in \( \text{Cu}_3\text{Al} \), all studied samples display two order-disorder transitions at high temperature and a martensitic transition at a lower temperature. In Cu-Al-Mn samples, it has been found that the order-disorder transitions are continuous from A2 to B2 and B2 to L2\(_1\) structures. In fig. 1 we present typical x-ray results together with the recorded thermogram. In contrast with these results, \( \text{Cu}_3\text{Al} \) undergoes a unique order-disorder transition from a disordered \( \text{(A2)} \) to a DO\(_3\) ordered structure.

The metastable phase diagrams for the two studied composition lines, showing the ordering tem-

temperatures and martensitic Mₘ temperatures as a function of Mn concentration are given in fig. 2a and 2b.

Regarding the martensitic transition, it is worth noting that the martensitic structure depends on e/a. The resulting structure has been identified by means of x-ray diffraction and it has been found that for e/a ≤ 1.46 the martensitic structure is 18R while for e/a ≥ 1.46 it is 2H [6]. The e/a values of the studied alloys have been calculated from their composition assuming that each Cu atom contributes with 1 electron, each Al atom, with 3 and each Mn atom, with 1 [7]. It is remarkable that we have detected the change from the 18R to the 2H martensite at an e/a value quite coincident with the e/a value at which the two phase boundaries of the high temperature bcc stability region in the equilibrium phase diagram [8] meet each other (eutectoid point).

3.2 Martensitic Transition
The entropy (ΔS) and the enthalpy (latent heat, L) changes at the martensitic transition have been obtained from calorimetric measurements after a proper correction of the calorimetric baseline as described in [9]. Within experimental uncertainties (evaluated to be less than 5%) no systematic differences between the ΔS values for forward (cooling) and reverse (heating) transitions have been detected. Therefore, we have computed the entropy difference between β and martensitic phases as an average of these two absolute values [6]. Since the martensitic structure depends on e/a, ΔS is likely to depend also on this parameter. In fig. 3 we have plotted ΔS as a function of e/a for all the investigated samples. The data exhibit a jump from a constant value ΔS = 1.26±0.06 J/K mol for e/a<1.46 up to a constant value ΔS = 1.51±0.05 J/K mol for e/a>1.46. Such a discontinuity occurs at an e/a value coincident with

that where the martensitic structure has been reported to change from 18R to 2H and, as previously mentioned, this is very close to the eutectoid point of the equilibrium phase diagram. In order to check whether this result can be extended to other Cu-based alloys, we have collected a large number of data from the literature for different Cu-based systems. These data are plotted (including present values for Cu-Al-Mn) in fig. 4 as a function of \( \alpha = e/a - (e/a)_{\text{eq}} \), where \((e/a)_{\text{eq}}\) corresponds to the eutectoid point. It is clear from the figure that \( \Delta S \) values collapse onto a single step function that changes from \( 1.31 \pm 0.10 \) J/K mol to \( 1.60 \pm 0.10 \) J/K mol at \( \alpha = 0 \). Present results render an entropy difference of \(\sim 0.3 \) J/K mol between the 2H and 18R martensitic phases, independent of the alloy system. This value is in good agreement with the values reported from stress-strain measurements [10-12].

The fact that \( \Delta S \) values for Cu-Al-Mn coincide (within the experimental errors) with those for other Cu-based nonmagnetic alloys, enables us to establish that a possible magnetic contribution to the whole measured entropy change should be very small. Hence, we conclude that for Cu-based alloys, the entropy excess of the \( \beta \) phase mostly stems from the vibrational degrees of freedom.

The enthalpy changes computed at the forward (cooling) and reverse (heating) martensitic transitions are shown in table 1. Their composition dependence shows a behavior similar to the one exhibited by the martensitic transition temperature. This is due to the fact that there are no significant differences among the entropy changes of the different samples. As is usual, the enthalpy change value obtained at the reverse transition is higher than that obtained at the forward transition, since the reverse transformation occurs at a higher temperature [9].

3.3 Quenching effects

The effect of quenches from different temperatures \( T_q \) up to 1080 K has been investigated in an A2 sample. In order to quantify the change in the transition temperature with \( T_q \), we have plotted in fig. 5 the temperature where the relative amount of martensite formed in the sample is 0.5 [13], \( T_{0.5} \), as a function of the quenching temperature \( T_q \). There is a marked decrease in \( T_{0.5} \) on increasing \( T_q \). The entropy change \( \Delta S \) is, within the experimental error, independent of \( T_q \). A decrease of the martensitic transition temperature with \( T_q \) has also been reported for Cu-Zn-Al [14], while an increase is observed for Cu-Al-Be [15]. However, in the case of Cu-Al-Mn the dependence of \( T_{0.5} \) with \( T_q \) is monotonous in the whole temperature range investigated, and the extrema observed for Cu-Zn-Al and Cu-Al-Be around the order-disorder transition temperature have not been detected here.

![Figure 5: Martensitic transition temperature dependence on the quenching temperature for the A2 Cu-Al-Mn alloy. ■: forward transition; ●: reverse transition. Open symbols: measured immediately after the quench. Solid symbols: after a 23-hour ageing at room temperature (\( \beta \) phase).](image-url)
This seems to be an indication that the mechanism which modifies the martensitic transition temperature in Cu-Al-Mn is different from the mechanism in other Cu-based alloys.

4. CONCLUDING REMARKS

The metastable phase diagram of β-Cu-Al-Mn has been obtained. Two continuous order-disorder transitions, from A2 to B2 and from B2 to L2₁ structures, have been detected. A martensitic transition occurs to a 2H structure for an e/a value higher than that of the eutectoid point and to a 18R structure for e/a less than this value. This is the general behavior for Cu-based shape-memory alloys.

The entropy and enthalpy changes at the martensitic transition have been measured. It has been found that the entropy change is a constant value that depends on the martensitic structure formed, and that there is an entropy difference of 0.3 J/K mol between the 2H and the 18R phases. It has been shown that these entropy change values are the same for all Cu-based shape-memory alloys. Then, it has been established that there is no significant magnetic contribution to this entropy change in Cu-Al-Mn.

Finally, the effect of quenches from different temperatures over the martensitic transition has been studied. Though they do not affect the transition entropy change, it has been observed that increasing the quench temperatures reduces considerably the martensitic transition temperature. It has been shown that this behavior is different from the one obtained in other Cu-based alloys.

Acknowledgments

Samples were kindly provided by M. Morin, INSA, Lyon (France). This work has received financial support from the CICyT (Spain), project MAT95-0504 and from the CIRIT (Catalonia), project SGR119. E.O. acknowledges financial support from DGICyT (Spain).
